Iris Anesthesia by Retrobulbar Injection and Paralysis of Orbicularis Oculi by Seventh Nerve Block. L. B. Somerville-Large.—p. 166.

**Intracapsular Extraction of Cataract.**—On the basis of his experiences in sixty-seven cases, Meyer enumerates the advantages of the intracapsular extraction of cataract thus: (1) applicability to immature cataract, which is technically easier than swollen mature cataract; (2) absolute lack of irritation of the eye during convalescence (this must be due to there being absolutely no capsule or cortex to irritate the eye, which remains quiet and white, showing no ciliary irritation whatever), and (3) early rupture of the lens capsule merely reducing the operation to the old and well known extracapsular extraction. The capsule ruptures either early or on delivery; in either case it does not matter. The author has never had one rupture half way, this is the operator's main fear; apparently it is groundless. The disadvantages of the operation are as follows: 1. Technically it is not so easy as the extraction out of the capsule. It is not a beginner's operation, but well within the reach of any surgeon of average capability. 2. The duration of operation is longer, owing to the injecting of procaine hydrochloride and the sewing of the conjunctiva, though the sedative and the procaine apparently keep the patient quiet, and the eye almost immobile. 3. There is no capsule to hold back the vitreous.

**Malignant Disease of Lungs.**—Kerley states that there are two equally common roentgen manifestations of primary lung cancer. In one a lung or a lobe is involved in a pneumonic process, and in the other the disease appears to be limited to the hilus. Certain roentgen features are common to the two forms, but as a rule they maintain distinctive appearances to the end. The appearances of the lobar or pneumonic form vary with the number of lobes affected. Contraction of the lobe, as evidenced by displacement of the fissure, was first noted by roentgenologists and led to a revision of the preroentgenologic idea that neoplasms of the lung increased the thoracic contents. Primary lung cancer by obliteration of bronchi and destruction of lung tissue always diminishes the thoracic contents. On closer study of a roentgenogram of a lobar carcinoma, it will be observed that the opacity is densest near the root and diminishes in intensity toward the periphery. If a very hard picture is taken, one can often distinguish two opacities: the first an extremely dense one attached to and spreading from the hilus, the second a less dense one covering the affected lobe in all directions. These two shadows represent growth near the hilus and collapse in the periphery of the lobe. If the vascular markings of the lung are invisible in the light peripheral opacity and visible in the dense opacity near the root, one can diagnose carcinoma with certainty, for their is no other lobar pneumonic process that produces this dual effect. In all nonmalignant pneumonic processes the lung markings are either completely invisible or faintly visible in every part of the affected area. Diaphragmatic paralysis is an invaluable sign. A less well known disturbance of innervation associated with carcinoma of the lung is compression or invasion of the vagus. Pleural effusion, as a complication of the pneumonic or lobar form of carcinoma, is the bugbear of the radiologist, for it masks nearly everything. If the effusion is small it has no significance, but if, as so often happens in malignant conditions, the effusion is large, one is confronted with great difficulties. The visualization of enlarged bronchial or mediastinal lymph nodes is one of the most valuable diagnostic points and is, moreover, of considerable clinical significance, since it contraindicates surgical intervention. An equally frequent roentgen manifestation of bronchial carcinoma is the so-called hilar form, which is seen as a dense opacity round the root of the lung without collapse or consolidation in the peripheral parts of the affected lobe or lobes. This type of the disease is easier to diagnose than the pneumonic type, because there are few other lung diseases causing similar appearances. A sudden transition from the hilar type to the pneumonic type is not uncommon, and probably if one saw the disease early enough one would find it first as a small hilar opacity later causing lobar or lung collapse. Obstruction of the superior vena cava takes place earlier and more often with a growth of the hilar type than with one of the pneumonic type. It is obviously impossible to describe all the varying appearances that are to be seen in roentgenograms of pulmonary carcinoma. But there is one roentgen feature common to all malignant growths of the lung: there is never normal lung tissue between the shadow of the neoplasm and the shadow of the mediastinum.

**Rectal Injury Caused by Faulty Enema.**—Rayner reports a case of injury of the rectum caused by the faulty administration of an enema. He suspects that the injury is by no means so rare as it is believed to be, and that the distress of inflicting it may befall any nurse. Because the mishap may have the most disastrous consequences and because it is entirely avoidable, attention should be called to it with some emphasis, even if it is a very uncommon occurrence. The injury is always a grave one, for it causes sloughing of the mucous membrane of the anal canal and rectum, and it is commonly necessary to perform a temporary colostomy in order to promote healing of the extensive raw surface left after separation of the sloughs. Sometimes, in consequence of the dense cicatricial stricture that follows healing, the colostomy may have to be a permanent one. In some cases death has resulted from sloughing of the rectal wall into the peritoneal cavity, or from spread of sepsis along the fascial planes of the pelvis. In addition to the gravity of the injury there is another important consideration—the legal aspect. The essential factor in the production of the injury is the use of a hard conical nozzle, usually of bone, sometimes of glass. The injury is caused by forcing the tip of the nozzle through the mucosa of the anal canal. Penetration of the mucous membrane by the nozzle tip may occur in certain circumstances without gross or unpardonable carelessness on the part of the administrator. Such circumstances, for example, as a poor exposure of the perineum from bad lighting and faulty position of the patient, insufficient lubrication of the nozzle, the use of some force to overcome the resistance caused by inaccurate insertion of the nozzle, and an everted condition of the anal mucous membrane, as in prolapsed hemorrhoids, may combine to trap the nurse, particularly if she is comparatively inexperienced and therefore handicapped by a feeling of awkwardness in the giving of an enema. The nurse, unaware of the perilous position of the nozzle—for the actual puncture of the anal mucosa gives the patient little pain—proceeds to inject a strong solution of soap and water into the submucous layers of the anal canal. The enema fluid strips up the mucosa of the anus and rectum over a large area, the extent of which depends on the amount of the fluid that has been injected. The injection of fluid under strong pressure into the submucosa causes such great pain to the patient that the nurse soon realizes that something is amiss and stops the enema, but not before some damage has been inflicted. The patient may experience a sensation of nausea and faintness, or he may even collapse, but in most cases these constitutional disturbances quickly pass off after the abandonment of the enema; so, too, the intense pain diminishes and becomes a mere discomfort or bearing-down sensation, of which the patient makes no complaint. At this stage, then, to the nurse there may be no visible evidence of the injury—no swelling and no bleeding from the anus—and she ascribes the patient's distress during the injection to some abnormal sensitiveness on his part, and so no report of the incident may reach the medical man.

**Displacement of Heart in Pulmonary Tuberculosis.**—From a review of the literature, Clayson concludes that the main causes of cardiac displacements in pulmonary tuberculosis are fibrosis and pleuropericardial adhesions, associated or not with a previous pleural effusion. Persistent afebrile tachycardia is not necessarily an indication of active disease and may be due to a displaced heart. When the roentgenogram shows a displaced heart, treatment should not be postponed till symptoms occur. A trial should first be given to breathing exercises, and then, if embarrassing symptoms develop, to phrenic evulsion. Displacements of the heart may possibly be prevented by the systematic practice of breathing exercises, begun as early as is judged to be safe.

**Treatment of Bone and Joint Tuberculosis.**—According to Dale, the modern conception of the pathologic changes in bone and joint tuberculosis divides the treatment of the disease into two equally important parts. The lesion in the bone or joint is regarded as being secondary (with the exception of a few cases of direct infection) to a lesion elsewhere, usually in the lymph nodes, often hidden from view, as in the bracheobronchial or retroperitoneal groups. The spread to the bone or joint takes place by the blood stream, the tubercle bacilli reaching the circulation by way of the lymphatics. The patient must be viewed in a dual light. He is suffering from a general tuberculous infection and a localized tuberculous lesion. The latter is a local manifestation of the former. Treatment that aims at correcting the local condition, while disregarding the general infection, is necessarily unsound. The two must be treated simultaneously and with equal persistence. Even the complete eradication of the local focus, by excision or amputation, does not cure the patient. If treatment of this general condition is not continued, the persistence of the general infection may manifest itself in a further local outbreak.

**Tuberculids.**—Low states that in investigations on tuberculids some observers have noted positive observations of tubercle bacilli, either microscopically or by animal inoculation. Others have obtained negative results; but from analogy, especially in the work done with ringworm fungus in producing microsporids and trichophytids and with favus fungus in producing favids, one is safe to assume that the tubercle bacillus is actually present in all tuberculids and can be found if the lesion is examined early enough. The reaction produced between the bacillus and the allergic skin is so great that within a short time the bacillus is destroyed. Probably in all cases of tuberculid, provided the lesion was removed within two or three days, the tubercle bacillus could be shown to be present. In cases in which negative results were obtained, the lesion was examined too late. Another well known fact also supports this view. After an attack of measles, the Pirquet skin test, although previously positive, becomes negative for some weeks or months. If, during that negative period, the child gets a blood infection with the tubercle bacillus, instead of the bacilli, which lodge in the skin, producing a tuberculid which would destroy them, they cause no reaction and are the starting point of multiple patches of lupus vulgaris. The author believes, therefore, that one may take it as proved that the tuberculid is a reaction between the tubercle bacillus itself and the allergic skin.

*Hemorrhagic Purpura Following Scarlet Fever: Report of Two Cases in One Family. A. G. Gibson and F. G. Hobson.—p. 509.

**Electrocardiographic Changes in Severe Diabetes.**—Smith and Hickling took successive electrocardiograms during treatment in twenty diabetic persons of all ages. These were at first at intervals of a few days, and later of weeks and months. The tabulated results showed that the most pronounced changes occurred in patients below the age of 40, the T waves being commonly flattened in leads I and II and often diphasic in lead III. Increasing amplitude of the T waves in leads I and II, and the substitution of an upright for a diphasic T wave in lead III, were the effects most frequently observed during treatment. In two patients, inversion of the T wave in all leads was recorded at the outset. All these changes disappeared progressively during treatment, whether by diet alone or by diet and insulin. The most uniform change and restoration was observed in lead II, while the T wave in lead III was more easily influenced by treatment and less stable in its form and direction. Other occasional electrocardiographic changes occurring during treatment were progressive diminution of the P wave and progressive lessening of slurring in the Q-R-S complexes. The causal factors underlying the changes described were considered under the following structural and metabolic heads: (1) coronary sclerosis, (2) coronary intimal fatty deposition, (3) abnormal metabolic products, and (4) defective nutrition of the myocardium. On the basis of their observations, the authors conclude that the electrocardiographic changes produced by diabetes represent mainly a parenchymatous damage to the heart resulting from defective nutrition. Coronary disease, whether sclerotic and permanent or of an early reversible fatty type, probably occupies a subsidiary position in the production of abnormal electrocardiograms.

**Staphylococcal Toxin.**—Panton and Valentine prepared toxic filtrates from twenty-two strains of Staphylococcus aureus. Their capacity to hemolyze rabbit red cells, necrose rabbit's skin and destroy the leukocytes in human blood was estimated. The results confirm the observations of others that the hemolysin and necrotoxin vary closely together with no relation to the leukocidin. The lethal action for rabbits, when investigated, was found to vary with the hemolysin content of the filtrate. Comparison with the human lesions indicates that strains yielding strong leukocidin and weak hemolysin are commonly associated with acute severe infections and the reverse combination with long-standing superficial infection of the sycotic type. The association of certain combinations of toxins with certain types of staphylococcal infection suggests differences in the specific treatment of these conditions. The employment of an antiserum is chiefly efficacious against pyemic infection, and the important antibody in the serum is probably the antileukocidin. Two sycosis cases were, on the contrary, both associated with a strong hemolysin and weak leukocidin. These cases notoriously respond badly to vaccine treatment and are sometimes made worse by it. There is also some suggestion that they do worse with an autogenous than with a stock vaccine. Treatment with toxoid in these and possibly in other staphylococcal lesions is more rational than treatment by vaccine, and in the sycosis the toxoid should contain leukocidin and possibly the minimum amount of hemolysin. The authors have treated only two such cases, but both were carefully selected as examples of extreme chronicity, widespread lesions, and resistance to every form of treatment. The result in both cases was sufficiently encouraging to test the method further. Immunization by toxin or toxoid is, in theory, preferable to vaccine therapy. The vaccine dose comprises a roughly calculated number of dead bacteria, and a very uncertain amount of toxins, mixed in quite unknown proportions. The dose of toxoid can be accurately measured, and by a choice of toxin the relative proportions of the different constituents can be chosen at will. The comparative values of toxin and vaccine treatment can be determined only by thorough clinical trial.

**Hemorrhagic Purpura Following Scarlet Fever.**—Gibson and Hobson enumerate thus the unusual features of two cases of hemorrhagic purpura following scarlet fever which they observed: 1. Purpura hemorrhagica as a late sequela of scarlet fever appears to be extremely rare. 2. This complication developed in two children of the same family, sixteen and twenty-one days, respectively, after an attack of scarlet fever which clinically was of a mild type and unaccompanied by any evidence of unusual toxemia. 3. While the mode of death was characteristic of death from hemorrhage, the actual loss of blood evident in the one case subjected to postmortem examination was small in comparison with the clinical anemia. 4. In contrast with the case reported by Box and Massingham, there was no reduction in the platelets. 5. It would seem possible to conclude only that in these children there existed some unusual constitutional susceptibility to the scarlatinal toxin.

Physiopathology and Semeiology of Tonicity of Heart: Myocardial Dystonias. N. Pende.—p. 73.
*Transitory Agranulocytosis with Pultaceous Erythematous Angina. M. Roch, Mlle. E. Perrot and A. Sierro.—p. 94.
*Ventricular Fibrillation as Unrecognized Cause of Death in Diphtheria. J. Chalier and R. Froment.—p. 102.
*Clinical Diagnosis of Acute Leukemia. M. Szour.—p. 110.

**Transitory Agranulocytosis with Pultaceous Erythematous Angina.**—Roch and his co-workers describe a case in which agranulocytosis had permitted a rapid development of pulmonary gangrene which resulted in death despite a change in the blood picture to polymorphonuclear leukocytosis. Their observation leads them to believe that the blood disturbance is primary and that the infected foci, in which the ulceronecrotic angina is most frequent, are secondary. In comparing the results of their study with the agranulocytosis as defined by W. Schultz in 1922, they state that their case has the following differences: Their patient is a man, whereas Schultz reports the disease as predominant in women. The angina does not have the habitual ulceronecrotic character but rather an erythematous and pultaceous character. In spite of the seriousness and the intensity of the agranulocytosis, the patient began to improve; death was due to pulmonary gangrene, and then a polymorphonuclear leukocytosis had succeeded the agranulocytosis. The agranulocytosis is transitory and not as pronounced as in the instances reported by Schultz. A marked presence of myelocytes in the blood leads one to suspect a relationship between leukemia and agranulocytosis. In conclusion, the authors recommend a classification for agranulocytosis which would include (1) the agranulocytosis of W. Schultz and (2) symptomatic agranulocytosis due to (*a*) septicemia, (*b*) intoxication, (*c*) roentgen radiation, (*d*) medullary disturbance: pernicious anemia, thrombocytopenia, acute, myeloblastic leukemia and, perhaps, myeloid leukemia.

**Ventricular Fibrillation as Unrecognized Cause of Death in Diphtheria.**—Chalier and Froment state that, during the course of diphtheria, at least two kinds of grave and sometimes fatal arrhythmias occur; the one is a blockade as a result of an auriculoventricular dissociation, and the other is the grave extrasystoles, which announce a ventricular fibrillation. The cardiac mortality in diphtheria is not over 10 per cent. Death caused by ventricular fibrillation during diphtheria can be not only sudden but even unexpected (a diphtheritic heart can pass in five hours from normal to ventricular fibrillation). The author finally says that ventricular fibrillation as an ultimate manifestation of such infectious diseases as pneumonia, poliomyelitis and bronchopneumonia is of minimum interest, since it is a detail of an agonal physiopathology rather than a clinical phenomenon. In diphtheria it is otherwise, since the ventricular fibrillation is manifested in the hours or the days preceding death and the prefibrillatory tachyarrhythmia may be one of the first and only signs for the prognosis of a fatal issue.

**Clinical Diagnosis of Acute Leukemia.**—After a discussion of two case histories, Szour concludes that the absence of pathologic lymphocytes does not distinguish an acute aplastic anemia from an acute lymphatic leukemia. Modern authors consider an acute leukemia as a general atypical reaction of the hematopoietic apparatus with toxic and bacterial factors. In a clinical study the diagnosis should be exact and as limited as possible, and a prognosis as certain as possible. The fact that very marked anemia can occur in the course of chronic, acute or contagious diseases that usually do not cause a grave anemia ought to be remembered in differential diagnosis and prognosis, since the anemia is an expression of a disease of the hematopoietic system or, better, a functional insufficiency of that system. Certain cases of acute leukemia can occur not only without manifestations of the hemorrhagic diathesis, without ulcerations in the mouth and elsewhere, without visible hypertrophy of the lymph nodes and the spleen, or increase in the number of white cells in the peripheral blood, but also without qualitative changes of the white cells in the peripheral vessels. The acute leukemia can last several months; the acuity of that disease is then a relative thing. The violence and the acuity of the evolution of the acute leukemia in some instances ought to be related to the terminal periods of that disease. The final periods are sometimes preceded by prolonged phases of hidden (occult) acute leukemia in which the more characteristic qualities are general prostration, anemia, a subfebrile state or, more frequently, slight oscillations in temperature. These signs are not characteristic for a definite disease; they do not give a solid basis for a diagnosis. The addition to the symptoms of bleeding of the gums or other bloody effusions may also in certain cases possess a value in differential diagnosis.

Ileocecocolic Resection in Two Stages for What Proved to Be a Posterior Appendicitis. R. Leriche.—p. 55.

**Benign Tumors of Pelvis.**—According to Tavernier and Pouzet, malignant tumors of the pelvis with the exception of sarcoma have, on the whole, a sharply defined character; roentgenograms of them are distinct and their evolution is rapid. The benign tumors of the pelvis are far different; they have generally a proteiform aspect in the roentgenograms, their evolution is slow, and they have a long latent period unless revealed by mechanical accidents. The authors report a fibroma, a myeloplaxoma, an unclassified tumor, an hydatid cyst, and two chondromas. In all the benign tumors, with the exception of the chondroma, the iliac bone is enlarged *en masse,* but one can distinguish two types, a spongy bone with a special trabeculation but without a destructive aspect (the fibroma, the undifferentiated tumor) and a spongy bone with cavities and zones of destruction (myeloplaxoma, and the hydatid cyst). The diagnosis of tumors of the pelvis may be very delicate but aside from secondary tumors and chondromas the tumors are easy to recognize when one has once seen the image. Outside of these cases and clinically it is a question of large spongy bone, which may be an osteosarcoma, a benign tumor, an inflammatory lesion and usually lesions in adolescents or young adults. The osteosarcoma evolves rapidly, generally with pain, and soon rarefies the ilium. The benign tumors, on the contrary, are insidious; there are no recognizable symptoms and the increase in volume is slow. The inflammatory lesions are usually cold or warm abscesses. Roentgenograms give the chondroma a special character: the mass adjacent to the bone has a cauliflower aspect with disseminated ossifications in the tumor. The series of benign tumors enlarge the ilium in a regular manner with variable trabeculation. The persistence of the cortex, even though deformed, is an apparent sign of benignity. Finally there is the large ilium, more or less spongy, with areas of destroyed bone. In the latter condition the diagnosis between osteosarcoma, hydatid cyst, and a myeloplaxoma is difficult; an explorative osteotomy may sometimes lead to serious accidents (the patient with a myeloplaxoma had a hemorrhage after a biopsy, infected his wound and then his tumor, and died). The prognosis is unusual because extirpation of tumors of the pelvis is difficult. The development, although slow, causes progressive alterations in the solidity of the pelvis and finally serious sequelae. Chondromas of the pelvis are not always benign and after a slow growth may suddenly increase in volume; removal is followed by recurrence. Extirpation of tumors of the iliac wing *en masse* would be ideal but, unfortunately, when they have spread to the hip the intervention becomes quite extensive. In every case resection is less grave than curettage of the lesions (the latter caused death as a result of shock in their patient with an hydatid cyst) and the cavitary surfaces are easily infected (the patient with a fibroma died of infection). When a complete operation cannot be performed it is perhaps best to refrain from operating because the patient may lead an active life for a long time despite the lesion, and the operative mortality is high.

**Calcified Bursitis.**—Naz and Kadrnka state that inflammatory conditions of the bursae are common, but rarely is there an evolution toward calcification. The better known calcified bursae are found in the subacromial and subdeltoid regions and are designated as scapulohumeral periarthritis or disease of Duplay. They discuss a personal observation of bursolithiasis. Roentgen examination revealed a far advanced stage of calcification. The localization and the image of the calcified bursitis involved the whole question of the diagnosis of infections of the elbow which are accompanied by an ossifying or calcifying hyperplasia and especially the capsular chondromatosis, which has been described but without anatomic verification. The bursolithiasis was subtricipital, the size of a small egg, first noticed about six months previously following a traumatism, and presented few clinical signs. The bursitis seemed to have been brought on by the peculiar work which the young woman was doing (ringing the church bells of the village). The case history, the pathologic anatomy and histology, the etiology, symptomatology, roentgenology and a classification for a differential diagnosis are discussed in detail. The authors state that the prognosis in calcified bursitis is generally good; the only thing to fear is the infection of the bursa and its perforation into the neighboring articulation. In a calcified bursitis a traumatism may produce an acute or subacute inflammatory process that is always aseptic; in that case, surgical intervention is an absolute indication and it should be early if one wishes to avoid a particularly rapid muscular atrophy. To avoid a recurrence, the extirpation of the bursa ought to be total and include the capsule in its entirety. In chronic cases, when the condition of the patient permits, one can try a conservative treatment whose duration will always be long and the result of which remains uncertain. The patient may be treated by diathermy, massage, mobilization, roentgen therapy and crenotherapy. Although good results have been reported with roentgen therapy, the authors recommend total extirpation as the treatment of choice.

## Paris Médical

1: 181-192 (Feb. 27) 1932

*Alimentary Anemias in Infancy. J. Cathala.—p. 181.
*Suppurating Gonococcic Thyroiditis Following Gonococcemia with Polyarticular Rheumatism and Gonococcic Nodular Erythema. C. Alexandresco-Dersca and D. Jonesco.—p. 188.
Aphorisms of Transthoracic Intrapulmonary Injection Called Lardage of Lung. G. Rosenthal.—p. 189.
Reduction of Shoulder Dislocation. A. Schwartz.—p. 191.

**Alimentary Anemias in Infancy.**—Cathala describes alimentary anemia as an evolutive type of curable anemia which at a certain age attacks some children submitted to certain diets. This anemia appears after the age of 6 or 8 months, is frequent at the end of the first and during the second year, and is not found any more after the third year. Although the time of its appearance coincides with the period of weaning there is no relation of effect and cause. It attacks especially certain children fed artificially and exclusively with excessive quantities (more than 1 liter) of cow's or goat's milk, and depends on some constitutional debilitating factor or a familial predisposition. Striking pallor of the skin and mucous membranes in an apathetic child, aged more than 6 months and less than 3 years, of regular weight and growth, but with flabby musculature and retardation of psychomotor development, will raise the suspicion of anemia, and a blood examination will establish the diagnosis. Splenomegaly may be present, auscultation may reveal fine crepitant and sibilant râles due to edema of the lungs, and there may be a slight rise in the temperature as a result of the nutritive disturbances. Often, but not always, alimentary anemia is associated with rickets; but there is no proportionate relation between the blood and the bone disturbances, and their respective treatments are totally different. Fever, rhinopharyngitis, bronchitis, pulmonary edema and even otitis accompany alimentary anemia, and dyspepsia or diarrhea is not uncommon. The hematologic formula is not specific but gives information on the degree and type of the anemia and on the reaction of the organism to the loss of red blood corpuscles. The author discusses the theories advanced by different authors to explain the occurrence of this anemia and outlines the treatment, which consists in an appropriate correction of the diet. The diet should be liberalized and completed with the juices of fresh fruits and vegetables, purées of green vegetables, meat juice, yolk of egg and stewed fruits, especially apples, the quantity of milk given being proportionately reduced. In complicated cases the necessary therapeutic measures must be instituted in order to obtain good results from the changed diet.

**Suppurating Gonococcic Thyroiditis.**—Alexandresco-Dersca and Jonesco report the case of a female patient suffering from gonorrhea with fever and very early gonorrheal localizations in the metacarpophalangeal articulation of the left and the right medius, the left radiocarpal and scapulohumeral articulations, the left elbow and the right knee. One week after the onset of the disease, localized pain on swallowing appeared in the right thyroid region with nocturnal copious perspirations, fever and chills. Painful polymorphous erythema nodosum lasting two weeks was a subsequent manifestation, while the right thyroid region was red, swollen and very painful on palpation: 12 cc. of pus was obtained from this region by exploratory puncture. Twenty-one autogenous vaccine injections, given subcutaneously one each day, combined with routine treatment have cured this patient.

7: 1-80 (Jan.-Feb.) 1932

*Tumors of Subhepatic Region: Eccentric Enlargement of Duodenal Outline. J. Didiée.—p. 5.
Reticulo-Endothelial System. C. P. Leblond and M. Ansel.—p. 16.
*Laboratory Research in Diseases of Liver. G. Parturier.—p. 24.
Study of Choluria Using Stalagmometry Combined with Hay's Test. L. Béthoux and P. Mounier.—p. 50.

**Tumors of Subhepatic Region.**—Didiée states that roentgen study of subhepatic problems assists sometimes materially in the localization and investigation of tumors; the modifications in the outline of the duodenum help to localize the abnormal mass found by palpation. The author describes a case in which roentgenographic in addition to clinical examination pointed to a large tumor lying entirely above the mesocolon and in addition retroduodenally to the inside of the duodenal circle, which it displaced eccentrically. Examination at necropsy showed a large, lobulated mass projecting into the duodenal outline, displacing the stomach upward and anteriorly and convex in front of the second and third portions of the duodenum; at this level the pancreas was visible, pressed against the anterior face of the tumor but remaining distinct from it. The mass extended to the posterior abdominal wall and enclosed the aorta, which traversed it from end to end. The rest of the abdominal cavity (especially the spleen) showed nothing abnormal. The cancerous mass was lardaceous and yellowish, with several areas of softening having the appearance of ecchymoses. The author concludes that the clinical history, the physical examination and the laboratory observations indicate a malignant tumor, deep in the subhepatic region, above the mesocolon, involving the connective tissue but no vital organ; the roentgenograms confirmed the clinical indications and localized the neoplasm at the level of the head of the pancreas behind and within the duodenal outline.

**Laboratory Research in Diseases of Liver.**—Parturier discusses the technic of duodenal intubation and its clinical applications in icterus and a painful syndrome without icterus. He concludes that duodenal intubation cannot in itself suffice to solve hepatopancreaticoduodenal problems; but its usefulness in a great number of cases cannot be denied. Its domain will certainly become extended when more is learned about the functions of elimination of the liver. Duodenal intubation may pass through the diagnostic and enter the therapeutic realm. Gastric or duodenal ulcers may be placed at rest; some authors, however, fear a method that brings a foreign body in contact with the lesion. Nevertheless the fact that considerable relief is experienced following the introduction of a duodenal tube and feeding through it may be considered as an argument in favor of an ulcer. Other authors have proposed and successfully used the same method in cholecystitis.

Sodium Bicarbonate and Citric Acid. F. Axmacher and H. Süllmann.—p. 236.

**Pharmacotherapy of Arteriosclerosis.**—Gordonoff ascribes the lack of an effective therapeutic method for arteriosclerosis to the fact that its etiology is as yet not fully understood, and that it is difficult to produce it in animals. But he further points out that Russian authors administered to rabbits cholesterol in sunflower oil and thus produced changes in various organs, but particularly in the aorta and in the larger arteries, which can be considered as an artificial sclerosis. The author employed this animal experiment to study the therapeutic value of various remedies that have been recommended for the treatment of arteriosclerosis, and he reports in detail his studies on the efficacy of chlorophyll. A series of control animals was given only cholesterol. A second group of animals was given chlorophyll and cholesterol. A third series was first treated for several weeks with chlorophyll, and then this was discontinued and cholesterol was given. To a fourth group he first administered cholesterol until hypercholesteremia had developed and then began to give chlorophyll. These experiments, the outcome of which is shown in charts and tables, revealed an antagonism between chlorophyll and cholesterol, in that the cholesterol content was reduced after chlorophyll administration. It is difficult to state to what this action of chlorophyll is due. The author is inclined to ascribe it largely to the reticulo-endothelial system, for not only does this system store cholesterol but recent researches indicate that it also takes an active part in the cholesterol metabolism. Chlorophyll is stored in the spleen, liver and lymph nodes, and it is possible that this pigment substance has a slight blocking effect and by thus inhibiting the function of the reticulo-endothelial system the resorption of cholesterol is partially or wholly prevented.

*Bilateral Subdiaphragmatic Resection of Vagus Nerves. G. Pieri.—p. 53.
Removal of Needle from Right Ventricle of Heart. V. Simeoni.—p. 60.

**Posttraumatic Jacksonian Epilepsy: Surgical Treatment.**—Alessandri, on the basis of many cases that came to operation, outlines his ideas on surgical treatment in cases of posttraumatic jacksonian epilepsy, which consists essentially in seeking to restore the local anatomic conditions as far as possible to the normal state. With respect to the bone lesion, it is necessary to reconstruct the irregular margins occasioned by the loss of cranial substance, and especially to remove shreds of tissue buried in the cavity, and to repair the breach with a flap derived from the external cortex and left adherent to the pericranium. If there is a cicatrix or absence of the dura, the latter should be replaced by a free autotransplant of fascia. If there is a cicatrix buried in the cerebral cortical substance, it should be excised and a free autotransplant of muscular tissue employed to arrest the hemorrhage and fill out the cavity. It is advantageous also, if the cranial teguments are too thin or too much scarred, to cover the pericranial bone flap with normal skin, which may be taken with a torsion flap from the adjacent tissues. On the basis of his clinical experience and experimental researches, the use of small fragments of muscle for hemostatic purposes on bleeding points of the cerebral cortex is preferable with heterotransplants (rabbit or pigeon). Also extracts of muscular tissue have been tried and have been found capable of marked hemostatic action, and have the advantage of being always ready at hand and not leaving any foreign body in the brain. After removal of cerebral tumors or cicatrices or opening of cysts in the cortical substance, it will be necessary to employ some hemostatic action and at the same time to fill the cavity. On the basis of three operations performed and of experimental researches, the author thinks that the best results are secured with muscular autotransplants.

**Intestinal Ureterostomy and Cutaneous Ureterostomy.**—Cilento studied experimentally the results of intestinal ureterostomy with various operative methods, and by means of functional control with methiodal he ascertained the behavior of the function of renal elimination following the intervention. He studied also the results of cutaneous ureterostomy and concludes that the latter operation is preferable and that in any event bilateral intestinal ureterostomy must be performed in two stages, and after having controlled the function of the opposite kidney by means of descending pyelography, following always the extraperitoneal route and the technic of the submucous implant.

**Bilateral Subdiaphragmatic Resection of Vagus Nerves.**—Pieri performed in man, in fourteen cases, bilateral resection of the vagus nerves below the diaphragm, for gastric disorders. He describes the peculiar anatomic features and gives his personal technic. By means of supra-umbilical median laparotomy combined with resection of the xiphoid process of the sternum, the abdominal segment of the esophagus was exposed; the peritoneum that covered it was incised transversely, and the branches of the vagus nerves were isolated and divided, the left vagus anterior to the esophagus and the right vagus posterior to the esophagus and to the right. The operation was always well tolerated and did not cause appreciable untoward incidents. In performing the operation, the author did not apply anesthesia to the nerve trunks nor supplementary gastro-enterostomy.

Action of Nephrogenic Toxins. V. Ghiron and S. Scandurra.—p. 645.
*Preferred Method of Cholecystectomy. E. Leo.—p. 655.

**Diagnosis and Prognosis of Acute Abdominal Syndromes.**—Trinchera, taking as his point of departure the results secured in one of his previous researches, repeated the same researches (chlorides and urea in the urine and in the blood; indican, acetones and biliary pigments in the urine) in a systematic manner, extending them in the clinical field to patients with acute syndromes of the abdomen: occlusions, hernial strangulations, generalized peritonitis. To control the clinical observations, similar experimental researches were carried out, provoking in dogs acute diffuse peritonitis and acute occlusions. From the ensemble of these clinical and experimental researches, the author was able to make the following observations: a constant and marked increase of the xanthoproteic reaction, the rose bengal test and the test for indican and bile pigments and of urea in the blood and of indican in the urine in acute intestinal occlusions; negligible changes in the chronic occlusion syndromes. The maximal increase of these values was found in the acute types of occlusion complicated by active peritonitis and in acute generalized peritonitis. In hernial strangulations the increase is moderate or slight in cases not followed by resection of the strangulated loop, while it is considerable in the cases in which such intervention is necessary. In dogs operated on for the purpose of producing simple occlusions, the author found at necropsy distention and moderate though very evident nutritional changes in the proximal stump.

**Preferred Method of Cholecystectomy.**—Leo criticizes the various methods of cholecystectomy, with and without drainage, subserous and otherwise. He attacks vigorously subserous cholecystectomy, giving his reasons for opposing it, and describes his own method of total cholecystectomy, without drainage, characterized by a new treatment of the gallbladder stump, which is covered with a pedunculated flap of the peritoneum of the gallbladder itself, or of the hepatic recess, to which peritonization, hemostasis and biliostasis by means of a special suture is applied.

*Deformation of Pupil Following Bilateral Pressure on Eyeball as Sure Sign of Death. L. Tonelli.—p. 205.
Clinical and Experimental Study on Use of "Avertin" as an Anesthetic. G. La Cava.—p. 210.
Dermoid Cyst of Mesentery. E. Cortella.—p. 217.

**Deformation of Pupil Following Pressure on Eyeball as Sign of Death.**—Tonelli states that the sign of deformation of the pupil after death is distinct and easy to elicit. In a living person (also in a state of apparent death), energetic pressure applied with the finger to two or more sides of the eyeball does not produce any modification of the round contour of the pupil, whereas, in a dead person, bilateral or plurilateral pressure applied to the eye, even though slight, produces, promptly, easily observable deformation of the pupil, the pupil becoming oval, triangular or polygonal, depending on the directions in which the pressure is applied. The author, on the basis of 655 observations, emphasizes the practical value of the sign of pupillary deformation as a reliable proof of death.

Roentgen Examination of Gastric Mucosa. H. G. Mogena.—p. 161.
*New Method of Lumbar Anesthesia, the So-Called Peridural Anesthesia. J. M. Martínez Sagarra.—p. 165.

**The So-Called Peridural Anesthesia.**—Martínez Sagarra describes a new method of lumbar anesthesia, the so-called peridural anesthesia, according to Dogliotti's technic (injection of the anesthetic into the epidural space, without perforation of the dura mater). The patient is prepared in the same manner as if he were going to be given spinal anesthesia. The level at which the injection is to be made is determined according to the region in which the operation is going to be performed. A short needle, mounted on a mandrin, is introduced slowly until it passes beyond the resistance offered by the yellow ligaments of the vertebral laminae. The mandrin is then detached from the needle while the latter is left in place. If cerebrospinal fluid does not ooze through the needle, it is an indication that the needle's point is in the epidural space, where the injection should be made. Without moving the needle, one connects a syringe of 10 cc. capacity, filled with 10 cc. of physiologic solution of sodium chloride, and slowly injects its contents. The epidural space offers no resistance to the injection. In case of resistance, a slight withdrawal of the needle places it in the proper location. Then a syringe of 50 cc. capacity (of the Luer type), filled with 50 cc. of a 1 per cent solution of procaine hydrochloride is connected. As the important point before giving the injection is to be sure that the needle did not perforate the dura and that the injection is made in the epidural space, only 10 cc. of the anesthetic is given first. The absence of symptoms, which commonly appear in five minutes in spinal anesthesia, gives one the proof of the proper position of the needle in the peridural space, and the injection may be slowly continued until the patient receives from 25 to 50 cc. of the anesthetic. The needle and the syringe are then withdrawn together. Twenty minutes should elapse between the injection and the beginning of the operation to obtain a complete anesthesia. During this time the patient is instructed to keep in the proper position so as to obtain the larger displacement of the anesthetic toward the nerve roots that supply the given operative area. Peridural anesthesia is safer and gives better results than spinal and paravertebral anesthesia because of the absence of shock and of postanesthetic complications (intense headache, due to the loss of cerebrospinal fluid through the opening of the puncture, and sometimes relaxation of the sphincters or retention of the urine), the simplicity of the technic by performing only one puncture, and its longer duration (more than three hours). Extremely nervous patients may present during the operation either slight nervous disturbances or a diminished arterial pressure and peripheral vasoconstriction with marked paleness. The inhalation of a few drops of ether or chloroform by the patient permits one to finish the operation without any more nervous disturbances, while the injection of 1 cc. of caffeine improves the arterial or vascular pressure. The method gives satisfactory results in 85 per cent of the cases. Its principal indication is for lumbar and upper abdominal operations.

Decrease in Tuberculosis Mortality. L. Ascher.—p. 341.

**Significance of Arterial Atony for Development of Arteriosclerosis.**—Plesch maintains that arteriosclerosis is only a partial manifestation of a systemic disease; that it is not restricted to certain parts but involves at once the entire vascular system; that the disease may develop in persons of all ages, and that it may be arrested. He thinks that during the early stage it is curable, and that even during the later stages it can be favorably influenced. It is not necessarily a disease of senility, which is progressive and incurable. Following these introductory statements the author brings, in the main portion of his article, first pathologico-anatomic proofs for his thesis. In discussing the etiology he expresses the opinion that every influence capable of weakening the organism so that a general atony results is a cause of arterial atony and of sclerosis. As a statistical argument in favor of his theory that arteriosclerosis is not necessarily a disease of senility, he cites the fact that it was found in many of the young soldiers who died during the war. Of the clinical proofs for his theses, he first discusses the blood pressure. He points out that the minimal blood pressure is one of the most reliable indicators of the condition of the circulation. In arteriosclerosis the minimal pressure is usually increased, even when the maximal pressure does not yet show a noticeable increase. For this reason the author advises that the term hypertension should be applied to the minimal pressure rather than to the maximal pressure. In regard to the quantity of blood, he states that it is generally increased. After discussing the roentgenologic signs on the aorta, he calls attention to one of the most characteristic symptoms, namely, the serpentine course of the temporal artery. Other symptoms that he discusses are angina pectoris, changes in the bulbus oculi and elevation of the diaphragm. As the first therapeutic measure the reduction of the blood pressure is recommended, which is more readily obtained if the patient lies down. It is also necessary to reduce the quantity of the circulating blood. In presclerotic plethora, venesection has proved valuable. But it is also possible to reduce the amount of blood by a diet with restricted amounts of nitrogen and of sodium chloride intake. In the majority of cases, cardiac stimulants can be dispensed with. Prolonged administration of small doses of potassium iodide is more harmful than good, but if arteriocapillary fibrosis has already set in, potassium iodide should be given in large doses (up to 8 Gm. daily) for about ten days. This treatment may be repeated two or three times at intervals of ten days. To counteract meteorism, the author recommends medication with tincture of asafetida.

**Aspects of Enterococcic Endocarditis.**—In the introduction, Rosenberg calls attention to studies by other investigators, which revealed that the clinical aspects of endocarditis lenta may exist although Streptococcus viridans is not present. He then describes a case of his own observation with the aspects of endocarditis lenta. In the course of the disease, several blood cultures were made. The pathogenic organism showed variable qualities, for in the first culture it showed characteristics that indicated its position between type A and type B of enterococci. The later cultures always revealed the type B enterococcus. It is emphasized that the term endocarditis lenta should be reserved for those infections of the endocardium which are caused by Streptococcus viridans. This demand is based on the experience that other pathogenic organisms, particularly enterococci, do not cause a typical endocarditis lenta as Schottmüller describes it. Endocarditis caused by enterococci differs from endocarditis lenta, especially in its pathologico-anatomic aspects, in that in enterococcic endocarditis the infarcts are infected, puriform and softened.

**Influence of Epinephrine on Diastolic Blood Pressure.**—Aalsmeer relates that in studying the blood pressure of patients with beriberi it was found that the subcutaneous injection of 1 mg. of epinephrine produced a peculiar circulatory manifestation, in that the maximal blood pressure increased only occasionally, whereas the minimal blood pressure decreased always systematically. This decrease was the more marked, the further advanced the disease was. The author found that this manifestation not only gave information about the type of the circulatory disturbance but also was valuable in determining the efficacy of a therapeutic measure, for, as the patient's condition improves, this sign gradually disappears. Since certain aspects of the circulatory disturbance of beriberi, such as increase in pulsation and the decrease in the minimal pressure, are also present in aortic insufficiency and in exophthalmic goiter, it was decided to make the epinephrine test also on patients with these disorders. It was found that the epinephrine reaction in patients with aortic insufficiency or with exophthalmic goiter showed, according to the degree of the disturbance in the peripheral circulation, a surprising similarity with that in patients with beriberi. The author thinks that the epinephrine effect in combination with the minimal pressure gives a better indication of the degree of the circulatory insufficiency than the so-called pulse pressure.

**Biologic Curve of Leukocytes as Indicator of Course of Disease.**—Schilling calls attention to the fact that, when the study of the leukocytic blood picture was first begun, it was assumed that certain pathogenic organisms produced typical changes, such as a monocytosis in malaria. But in due time it was recognized that the main characteristics of a blood picture were not determined by the type of the pathogenic organism but that the various phases of the biologic curve of the leukocytes corresponded to certain reactions of the patient's organism. It was found that during the progressive stage of the disease neutrophilia predominates, at the time of the crisis there is a monocytosis, and during the period of convalescence there is an increase in the lymphocytes and in the eosinophils. These three phases correspond to the reactions of the three defense systems of the organism; namely, the bone marrow, the reticular monocytic system and the lymphatic system. After thus explaining the foundations of the simple biologic curve, the author shows the course it takes in the event that the virulence or special development of the pathogenic organism leads it into different routes. As an example he takes the artificial malaria infection. He further discusses the significance of the leukocyte curve in gynecology. During a normal delivery the leukocyte curve usually presents the aspects of a mild infection or of a slight injury. Considerable changes are noticeable during septic puerperal processes. If an infection takes a malignant course, the blood picture shows a constantly increasing neutrophilia, and this tendency is not interrupted even during a surgical intervention. The author further shows the significance of the leukocyte curve during such conditions as sandfly fever, benign erysipelas, recurrent fever, measles, pneumonia, typhoid, tuberculosis and even psychic disorders. In the conclusion he refutes the statement that this form of examination of the blood is too specialistic. He emphasizes that it is a reliable method of observation at the bedside, and that it gives indications for therapeutic measures.

**Intracranial Hemorrhage During Birth.**—Catel shows that, with the aid of the simultaneous quantitative determination of bilirubin in the serum and in the cerebrospinal fluid, it is possible to diagnose intracranial injuries received during birth while the child is still alive. Although the number of cases in which this was possible is as yet not large, the method has the advantage that it is based on a reliable foundation. Observation proved that, even when the course of birth is normal, intracranial hemorrhages are comparatively frequent, but symptoms in the form of a lack of vitality are present only in about one half of these cases. In spite of the fact that a first birth and a pathologic course of the birth (use of forceps or breech presentation) favor the development of birth injuries, the author considers it as not permissible to conclude from the birth anamnesis alone the presence or absence of a birth trauma. In a child that has been delivered by means of forceps or from a breech presentation and that later shows symptoms of Little's disease or of imbecility, it is not right to assume without reservation a causal relation between the two factors, as is often done by pediatricians and neurologists. The author admits that extensive intracranial injuries sustained during birth may be a direct cause of death or may lead to cerebral injuries that become manifest at a later date, but on the basis of his observations he considers it as out of the question that the birth trauma has significance as a cause of death or as a cause of late central nervous disorders which have been ascribed to it in recent years. Postmortem examinations revealed that, in 6.6 per cent of the children, death was a direct result of birth trauma, and after-examinations in children who were severely injured during birth showed that the further development was generally unimpaired.

**Cause of Death in Premature Births.**—Creutzfeldt and Peiper describe the results of the histologic examination of the brains of seven premature infants, who all had shown before death serious respiratory disturbances. Six of them revealed no hemorrhages whatever in the brain stem, and in the seventh child there were small extravasations without reactions of the surrounding tissues, that is, so-called agonal hemorrhages. In this case there also was a slight hemorrhage from the right vena terminalis. These observations contradict the assumption of Ylppö, of Schwartz and of others who believed that the fatal respiratory disturbances in premature infants must be the result of cerebral hemorrhages. On the contrary, the observations prove that death is only the result of the immaturity of the central nervous system and of the resulting weakness of the respiratory center.

**Treatment of Whooping Cough by Means of Bordet Vaccine.**—Induced by the hygiene commission of the League of Nations, Weichsel employed the Bordet vaccine in the treatment of fifty cases of whooping cough. All the children were in the early paroxysmal stage. There was no opportunity for a prophylactic use of the vaccine during the incubation period. Those children in whom the paroxysmal stage had begun more than two weeks previous were excluded from the vaccination. The Bordet vaccine consists of a culture suspension of killed Bordet-Gengou bacilli in ampules containing 1 cc. each. Six injections are supposed to be sufficient to check the whooping cough, and they were administered at intervals of forty-eight hours. Since no special directions were given as to how the vaccine was to be administered, the author made some of the injections subcutaneously and some intramuscularly. Local and general reactions were entirely absent in either form of administration. A therapeutic effect of the vaccine was not noticeable.

**Pathogenesis of Diabetes Mellitus.**—Pollak discusses the question whether diabetes mellitus is always a pancreatic diabetes, more particularly an insular diabetes, or whether there are also cases of extra-insular origin. He calls attention to certain contradictions in galactose and dextrose assimilation, which he terms the galactose paradox of diabetes, and describes the tests he made to determine the mechanism of certain processes in the sugar metabolism. The last group of his experiments he sums up as follows: A galactose tolerance test produces in diabetic patients a considerable increase in the dextrose content of the blood. This indicates elimination of enormous quantities of sugar by the liver. Ergotamine tests revealed that in diabetic patients, just as in persons without diabetes, the glycosecretory impulse comes from two distinct endocrine glands. Both types of impulses are found in entirely different forms of diabetes. If these conditions are to be traced to a common cause, the author considers only one explanation possible. The glycosecretory impulses are the same in persons with or without diabetes. That in diabetic patients there is a much greater increase in the dextrose content of the blood must therefore be due to the fact that in diabetes there is no checking influence of insulin, which otherwise reduces the stimulation susceptibility of the liver.

**Chronic Hepatogenic Hypoglycemia During Childhood.**—Van Creveld relates the clinical history of a boy, aged 10, in whom a chronic hypoglycemia had been observed for several years. This hypoglycemia is noticeable during fasting and it is combined with ketosis. The patient gives the impression of having adiposogenital dystrophy, and he also has an unusually large liver, the abnormal size having been noticed during the first year of life, when an exploratory laparotomy was done. The chronic hypoglycemia in this patient is different from the great majority of other cases that have been described, in that such symptoms as anxiety, hunger, rapid pulsation, trembling, spasms, dizziness, coma and reduction in blood pressure are entirely absent. The metabolism also shows typical differences from other cases of chronic hepatogenic hypoglycemia. Numerous experiments were made to gain a better insight into the metabolic disturbances of this patient. The existence of hyperinsulinism can be excluded almost with certainty. The ketosis was unfavorably influenced by epinephrine, even when the latter was given in minute quantities. As the origin of the complicated disturbance the author assumes the persistence of a fetal condition, and as proof for this assumption he cites the fact that in premature infants acetonuria and also hypoglycemia are much more frequent than in mature ones. This of course does not explain the disturbance in the reported case, but here the author sees the cause in a disturbance of the fermentative decomposition of the liver glycogen and perhaps also of the glycogen in other organs. The glycogen content of the blood was increased.

**Action of Toxic Component of Viosterol (Calcinosis Factor) on Bone Phosphatase.**—Bischoff and Loeschke found that greater doses of the calcinosis factor are tolerated by rachitic dogs than by normal dogs. The bone phosphatase is reduced by the calcinosis factor in normal as well as in rachitic animals. In rachitic dogs, the calcinosis factor increases the calcium and the phosphorus values of the serum. Simultaneously with this chemical regulation of the blood, calcium is deposited in the bones.

**Subepiphyseal Zones of Decreased Density in Roentgenogram of Nursling.**—György reports that in a nursling, aged 10 months, who was free from rickets, generalized edema developed in the course of an intensive antirachitic treatment, with signs of a renal disturbance of a mostly tubular character. Simultaneously in the long bones there became noticeable subepiphyseal areas of lessened density, such as are observed only in animals that have been treated with large doses of viosterol and have received a diet deficient in calcium. After the antirachitic treatment was discontinued, the osteoporotic zones of decreased density extended in the direction of the diaphysis and were noticeable for several months. The author discusses what significance these observations have for the intermediate calcium metabolism.

*Cytology of Pus in Gonorrhea in Men. L. R. Leites and D. G. Tulbermann.—p. 111.

**Cytology of Pus in Gonorrhea in Men.**—Leites and Tulbermann studied the ratio between the various types of pus cells during the different stages of gonorrhea and during the various complications. Their object was to detect in the gonogram a diagnostic aid similar to the spermoculture method or to gonococcus antigen determination. A difficulty in the study of the gonogram is that there is no normal pyogram as a basis of comparison, pus being always a pathologic condition. For this reason it was necessary first to determine certain threshold values. As such the authors considered for the eosinophils from 0.1 to 0.4 per cent; for the young forms from 0.1 to 0.6 per cent; for the staff nuclear cells (monocytes and lymphocytes) from 0.1 to 0.9 per cent. The method of examination was as usual. After the fresh smears had been dried in the air, they were fixed for fifteen minutes in alcohol and ether and then stained for twenty minutes in a Giemsa solution. The authors examined material from ninety-two patients and made in all 500 tests. In some of the patients the pus was examined only once or twice. In another group of thirty-two patients the pus was regularly examined from the beginning of the disease until there was no longer any discharge (from ten to twenty times in a period of several weeks). In cases of gonorrheal prostatitis the secretion of the prostate was likewise examined. Of the ninety-two patients, fifty-four had acute uncomplicated gonorrhea, nine acute epididymitis, twelve acute prostatitis, seven chronic gonorrheal urethritis, five chronic postgonorrheal urethritis, three chronic prostatitis and two nongonorrheal urethritis. In classifying their material according to weeks, the authors aimed to detect a characteristic gonogram during the same clinical stage, and they also tried to determine whether a change in the treatment had an influence on the cellular composition of the pus. The results of the investigations are shown in tables.

**Value of Ergot in Puerperium.**—On two groups of fifty-three puerperas each, Sühs made tests to detect the therapeutic and prophylactic value of ergot. During the first three or four days of the puerperium the first group received eight drops of an ergot solution, three times daily, for prophylactic purposes. To the other group the ergot was administered only when disturbances developed in the involution. It was observed that, in the women who had received prophylactic ergot treatment, disturbances in the discharge of the lochia and in the involution of the uterus were less than half as frequent as in the women who had not been subjected to prophylactic ergot application. An entirely undisturbed course of the puerperium was observed in only 6 per cent of the women who had not received prophylactic treatment; but in those who had been subjected to the ergot prophylaxis, the course was normal in 57 per cent of the cases. The author thinks that this is a conclusive demonstration of the prophylactic value of ergot during the puerperium. When the ergot solution was administered only after the disturbances became manifest, it was noted that in one third of the cases the course was almost the same as would be expected without therapy, but in two thirds of the cases there was a favorable effect on the involution of the uterus and its attendant phenomena.

Denicotinization of Tobacco Smoke. J. Nikolowowa and Z. Wójcik.—p. 164.

**Histamine in Arterial Hypertension.**—Koskowski states that histamine is antagonistic to epinephrine. Excess of histamine stimulates the suprarenals to increased secretion. Both substances exert their action on the blood vessels. The author's experiments show that ordinary intravenous injections of histamine cause a considerable and characteristic fall of blood pressure. Very slow injections, however, of greatly diluted histamine increase the blood pressure slowly but constantly. By previous experiments the author, jointly with Giedroyć, demonstrated that the red blood cells are the carriers of epinephrine and that they are capable of storing it up. The substance causing this excess of epinephrine in the blood is histamine. By causing hyperepinephrinemia, histamine is then indirectly responsible for certain cases of hypertension. Thus one of the therapeutic problems in these cases of high blood pressure is to select the diet so that the proteins digested produce a minimum amount of histidine, which is the source of histamine. It is known that animal myosin, globin, casein and so on contain histidine. In view of the foregoing problem, it would be logical to review next the plant proteins for the amount of histidine contained.

**Urea Tolerance Tests in Hypertrophy of Prostate.**—Hellstadius calls attention to the fact that urea tolerance tests have been used for testing the renal sufficiency in cases of hypertrophy of the prostate with the view of obtaining information regarding the renal capacity for excreting urea in cases in which the nonprotein nitrogen in the blood is not obviously increased. In comparing the outcome of the urea tolerance and the water tests, one generally obtains a certain agreement between the two; but in some cases there is noticed an obvious discrepancy between the two tests. It may be of advantage, therefore, at least in doubtful cases, to carry out a urea tolerance test besides the water test. There is no reason to conclude that the uric acid in the blood would increase earlier than the nonprotein nitrogen in an early stage of renal insufficiency, at least as far as it can be ascertained by the urea tolerance test.

**Tuberculosis and Hypernephroma of Same Kidney.**—Ljunggren describes a case in which a Grawitz's tumor (hypernephroma) and tuberculosis were present in the same kidney. He found seven similar cases in the literature. In his view it is most natural to assume in these cases that it was a coincidence that the two conditions occurred simultaneously, but he nevertheless thinks one has to take into account the possibility of a renal tumor predisposing to the development of a tuberculous process in the kidney. That the tuberculous infection would in any of the cases have been the primary factor, and secondarily given rise to tumor formation, he considers unlikely. One would rather contemplate the possibility of a tumor predisposing in some way or other to the development of a tuberculous process in the kidney; in a case that he observed recently, for example, one can envisage that the circulatory disturbances which experience shows exist in the renal parenchyma in the proximity of a tumor create a locus minoris resistentiae.

# LEG ULCERS OF UNRECOGNIZED ETIOLOGY

NORMAN J. KILBOURNE, M.D.
Attending Surgeon, Los Angeles General Hospital
LOS ANGELES

In a series of 150 cases of leg ulcer, seen in clinic and in consultation, 50 patients were found in whom varicose veins were not visible and the Wassermann reaction was not positive to point to the cause of the ulcer. Ulcers with no obvious etiology present a neglected problem in diagnosis.

The clinical picture is distressing: the patients are incapacitated for self-support; they are unable to sleep at night for pain; they go unhealed for five years, ten years, twenty years, even thirty-eight years!

The past histories of these fifty cases showed that the average practitioner is puzzled to know what to do with them. He tries ointments, light treatments or ingenious surgical procedures to the part. Improvement is temporary. Eventually the old ulcer breaks down again or new ulcers form because the original cause of the ulcer has not been ascertained.

In my experience, a way out can usually be found in a discovery of the causes of the ulcers. The whole series is listed in an analysis of causes, in order that practitioners may have it available for reference, in considering possible explanations of a difficult ulcer case. Some cases due to more than one cause are entered twice in the list. Out of the list, only those types will be discussed which have not been found reported in the literature or which I have found to be commonly unrecognized.

### THE LACUNAR ULCER

There is a type of ulcer, rarely recognized, whose cause is found in invisible varicose veins, too deep in the tissues even for palpation, but which may be demonstrated by x-rays after intravenous injection of such radiopaque substances as iopax (uroselectan). Such roentgenograms or phlebograms are shown in figures 1 and 2. They demonstrate positively the cause of ulcers which otherwise might never have been diagnosed. Although only seven are included in the list, I am increasingly impressed by their importance and believe that in other cases such roentgenograms would have demonstrated this cause as at least contributory. The term "lacunar" is suggested for this type because the ulcer is due to a lake of stagnant blood in veins beneath or near the ulcers.

The indications for taking a phlebogram may be:

A history of obliteration of small varicose veins higher in the leg without curing the ulcer.

A history of phlebitis long ago, even though no varicose veins are visible.

A slight sense of fluctuation in the region of the ulcer.

The presence of varicose veins visible in the other leg.

The use of iopax for this purpose has been described thus far in the continental literature only. Its use as a radiopaque medium in the veins was first made by Ratschow.[1] Warning should be given against the present use of iodized poppy-seed oil into the veins for roentgenologic demonstration. Ratschow did this in dogs. From ten to fourteen days later the dogs died of pneumonia, and sections of their lungs stained with sudan III showed minute fat emboli scattered through the lungs as the cause of death. Iopax has now been used in so many thousands of cases for pyelography that its safety is demonstrated. There are two methods: injection from above, and injection from below. In injecting from above, the usual procedure is to insert the needle into the great saphenous vein just below the knee. However, there is an important valve in the vein here which is commonly competent, and I have found that injection is made better below this valve about one third of the way down from the knee. Sometimes it is impossible to inject from above, and I have then utilized a method of my own. While the patient stands, a rubber bandage is bound around the leg, beginning at the ankle and winding upward in a spiral

*Various Causes in One Hundred and Fifty Cases of Chronic Leg Ulcer to Dec. 5, 1931*

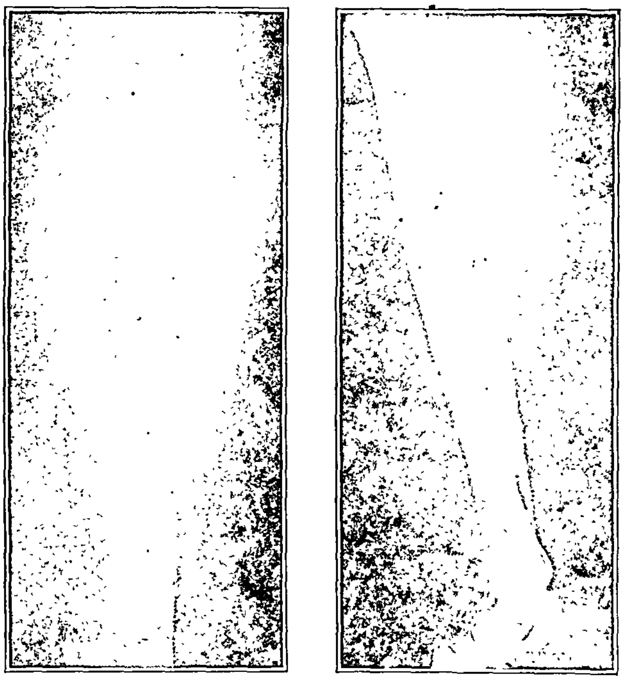
without overlapping the edges of the bandages. This empties the superficial veins and at the same time makes the veins of the foot stand out. A 24 gage needle on a 20 cc. Luer syringe containing 30 per cent iopax is then inserted into the most prominent vein of the foot. With the needle still in place, the patient lies down. The rubber bandage is now unwound from below upward. Sometimes it is left on just below the knee as a light constrictor. Injection is then made and x-ray shadows are photographed immediately and again fifteen seconds after injection. The injection is slightly painful if the constrictor is left on. No slough occurs if iopax is injected out of the vein.



Figs. 1 and 2.—Invisible varicose veins causing lacunar ulcers.

Treatment of the lacunar ulcer requires the injection of any veins visible above the ulcer whether they are varicose or not, and the application of McPheeters'[2] sponge heart. Early experience in my clinic with the sponge heart was unsatisfactory: The skin surrounding the ulcer broke down under the pressure of the rough sponge, forming new ulcers. Since I put an abdominal pad of cotton between the sponge and the leg, the results have been excellent. The patient is urged to walk as much as possible, for every movement of the muscles presses on the sponge, which in turn squeezes blood out of the veins. The tissues soften so that unseen veins become barely palpable as a slight sense of fluctuation. Injection of these brings permanent cure. Sometimes the only place where the veins become accessible for injection is surprisingly superficial in the layers of the thickened skin itself. The injection of such veins is difficult and requires long experience.

Figure 3 shows a lacunar ulcer which had been treated by skin grafting by an excellent plastic surgeon. The operation was a perfect piece of work and the graft "took" without a break. The result was beautiful. But when the patient was on his feet three weeks later the graft broke down. This illustrates my insistence on etiologic treatment.

A roentgenogram of the venous circulation demonstrated the cause of the trouble in invisible varicose veins.

### ARTERIOSCLEROTIC ULCERS

In ulcers due to obliterating arteriosclerosis the diagnosis is made by digital examination of the dorsalis pedis and tibialis posterior arteries. If arterial pulsation is not present in either of these arteries to the foot, the chances are strong that the ulcer is due to arterial disease. Sometimes the toes and foot have a waxy pallor. It should be remembered that the terminal arteries to the skin of the lower leg commonly sclerose long before the terminal arteries to the toes. Eloesser[3] has described these ulcers. He advised amputation of the leg, but in my cases there have been cures or steady improvement without sacrificing the limb.

Many of these patients should be given the benefit of the doubt and receive a therapeutic test to rule out Wassermann negative syphilis as the cause of the obliterating endarteritis.

In two cases in which there was no pulsation whatever in the arteries, amputation had been proposed. However, I insisted on a therapeutic test of injections of a bismuth compound, even though the Wassermann test was negative. In both cases the ulcer has healed and has stayed healed and the leg has been saved. In both cases pulsation has returned to the dorsalis pedis artery.

When the therapeutic test fails or when great age makes it clear that the arteriosclerosis is senile, improvement has been obtained by bed rest, by the use of diathermy with one pole at the sole of each foot, by massage, by frequent massive hot compresses, by supporting bandages, and by the use of thiocresol[4] solution or of insulin locally. I am opposed to ligation of the vein in these cases, for reasons already stated.[5] Sympathectomy is also inadvisable.

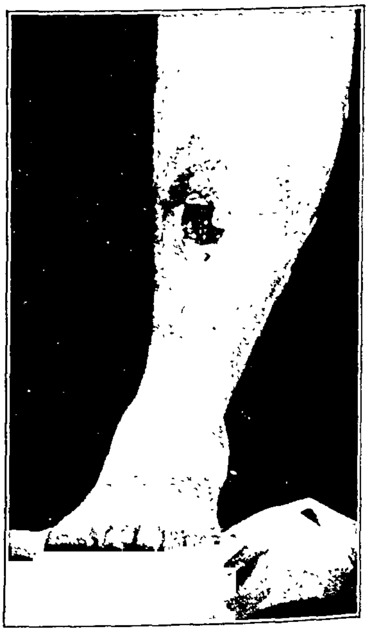


Fig. 3.—Lacunar ulcer.

### ULCERS CAUSED BY ENDOCRINE DEFICIENCY

*Hypothyroidism.*—I have not found in the literature such a case as this reported:

A housewife, aged 42, had had an enormous ulcer on the lower part of the right leg as large as an outspread hand for seventeen years. It caused her great pain, especially when she was obliged to stand, so that she was a dependent on her relatives.

---

[2] McPheeters' sponge heart will go down through medical history as a major contribution to surgery. McPheeters, H. O., and Merkert, C. E.: Varicose Ulcers: Treatment with Rubber Sponge or Venous Heart, Surg., Gynec. & Obst. **52**: 1164 (June) 1931.

[3] Eloesser, Leo: Leg Ulcer, S. Clin. North America **2**: 537-552 (April) 1922.

[4] Reiman, S. P.: Use and Reasons for the Use of Thiocresol to Stimulate Wound Healing, J. A. M. A. **94**: 1369 (May 3) 1930.

[5] Kilbourne, N. J.: Varicose Veins: Indications and Contraindications to Injection, Ann. Surg. **93**: 690 (March) 1931.

The past history of the patient was irrelevant with the possible exception of phlegmasia alba dolens six years before the ulcer appeared.

The patient was 39 pounds (18 Kg.) overweight. There was an enormous pituitary apron. Adipose tissue was marked both above and below the elbows and knees. The affected leg was larger than the left leg even above the knee, so that the right thigh was 4½ inches (11.5 cm.) larger in circumference than the left. The blood pressure at this time was 150 systolic and 95 diastolic. The pulse was 70. The ulcer covered most of the lower portion of the anterior part of the leg and was very deep with steep walls. The surrounding tissue had an edema which allowed pitting on pressure.

A previous diagnosis of varicose ulcer had been made although no varicose veins could be found. Twenty-two Unna's paste casts had been applied without improvement.

A basal metabolic rate was requested. The report came, "We cannot determine the basal metabolism of this patient."

"Why?"

"Because her rate is so low that it cannot be registered on the basal metabolism apparatus."

Fifteen grains (1 Gm.) of thyroid per day was prescribed and no local treatment. In ten weeks this ulcer, which had lasted almost a quarter of a century, was healed, being filled in with firm solid thick skin!

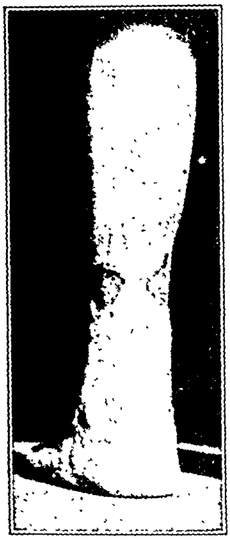

Fig. 4.—Arteriosclerotic ulcer, senile type.

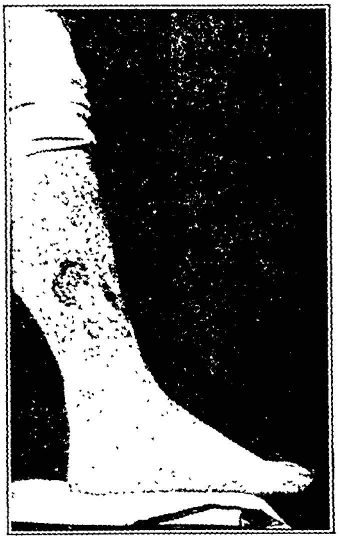

Fig. 5.—Arteriosclerotic ulcer (half healed), senile type.

The ten weeks of thyroid medication caused the systolic blood pressure to drop 72 points to a reading of 78 and the diastolic to drop 11 points to a reading of 54. The pulse slowed as the patient received thyroid, dropping from 70 to 60.[6]

*Hypo-Insulinism.*—In at least eight cases, a lack of insulin secretion contributed to the chronic ulcer, as evidenced by the blood sugar. Several of these were complicated by recurrent attacks of cellulitis.

## ULCERS OF PROFOUND ANEMIA

*Primary Anemias.*—In hemolytic icterus,[7] splenomegalic anemia[8] and sickle cell anemia, leg ulcer is a classic symptom.

A negro chauffeur, aged 22, had had an ulcer of the leg for five and a half years. It caused pain both at night and in the daytime when he tried to walk very far.

Other symptoms were absence of libido, lightning pains in the legs, productive cough, pain in the abdomen, and loss of 10 pounds (4.5 Kg.) in the past three weeks.

A year before a diagnosis of varicose ulcer had been made. For a year he had been receiving repeated applications of Unna's paste casts. The casts seemed to relieve the pain for the first two days after application, but after that the pain would be worse. He had not improved under this year of Unna's cast treatment. More recently it had been diagnosed as a syphilitic ulcer.

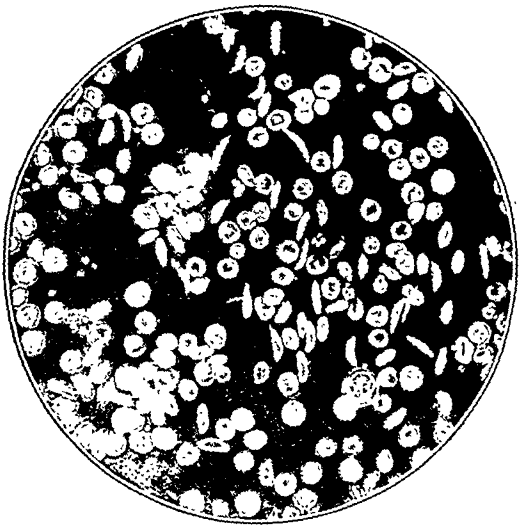

Fig. 6.—Sickle cell anemia.

The patient was very thin, with thin long fingers and extremities remarkably long in comparison with the body. The lower extremities were 22 cm. longer, as compared with the body, than one would expect from average measurements.

Laboratory examination produced three negative Wassermann reports even after provocative injection of neoarsphenamine. A roentgenogram of the right tibia showed no periostitis, syphilitic or otherwise. The sputum was purulent but contained no acid fast bacilli, and roentgen examination of the chest showed no material pulmonary pathologic changes. The urine contained a few pus cells and hyaline casts. Chemical examination of the blood showed an icterus index of 17.7 but otherwise was normal. The hemoglobin was 54 per cent; the red blood cell count was 3,600,000, the white blood count 20,000.

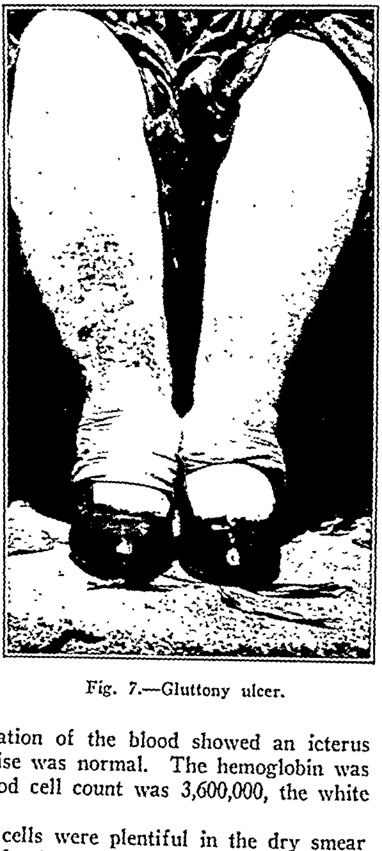

Fig. 7.—Gluttony ulcer.

Crescent-shaped sickle cells were plentiful in the dry smear and are shown in figure 6. A standing wet mount showed the usual increase in their number to 50 per cent of all red corpuscles. The patient's mother also had her blood examined and it showed sickle cells after standing thirty-six hours in a wet mount.

---

[6] This patient drifted away and stopped taking thyroid. Five months later she had a small recurrence. Thyroid alone did not immediately cure this recurrence. A phlebogram taken by x-rays with iopax injected through the veins of the foot showed deeply buried varicose veins which were contributory to the recurrence.

[7] Seelig, S., and Jaffé, Kaete: Unterschenkelgeschwüre bei hämolytischen Ikterus, Klin. Wchnschr. 9:840 (May 3) 1930. Eppinger, Hans: Ueber schwer heilbare Fussgeschwüre bei hämolytischen Ikterus, ibid. 9:10 (Jan. 4) 1930.

[8] Nanta, A.: Les ulcères de jambe des splénomégaliques, Bull. Soc. Franç. de dermat. et syph. 35:946 (Dec.) [illegible] and Emile-Weil, Prosper: Les ulcères de [illegible] Bull. et mém. de la Soc. nat. de chir. 55:91-94 (Feb. 2) 1929.

The ulcer of the leg was of course diagnosed as the ulcer classically associated with sickle cell anemia.

Sickle cell anemia has been presented as a disease peculiar to the Negro race, presenting clinically two surgical features: attacks of acute abdominal pain, and chronic leg ulcers.

For a year this patient was treated medically. The ulcer would not stay healed. Then the veins of the leg appeared rather more prominent than a year before and the ulcer grew rapidly. One injection of quinine-urethane was given in the great saphenous vein above the ulcer. The result was the most rapid healing of an ulcer I have seen. Obviously the veins were the cause of the ulcer, and probably there had been deep veins there as causative factors even when the superficial veins were not obvious. The treatment with Unna's paste casts had not been a reliable therapeutic test.

This is only one case, but it raises the question as to whether there is any essential direct connection between sickle cell anemia and leg ulcer as has been so long taught.

tration of 90 grains (6 Gm.) of iron and ammonium citrate. This cured the ulcer.

A gilder, aged 61, had had an extensive ulcer of the right leg for five years. In the past year he had had 208 large dressings with an ointment without improvement. The patient's physician suggested syphilis as a diagnosis, but improvement under antisyphilitic treatment was not impressive. The hemoglobin proved to be 45 per cent. His mouth contained old tooth snags, which were not only toxic but also prevented mastication of his meager diet. He refused to have his teeth removed but consented to take massive doses of iron. The ulcer has improved rapidly, *pari passu* with a rise in hemoglobin.

A third patient, whose anemia was due to uterine hemorrhage, was cured when this was corrected.

It is unreasonable to expect to cure a chronic leg ulcer with ointment, lights or skin grafts when a patient has a hemoglobin ranging from 40 to 55 per cent.

### GLUTTONY ULCERS

In three obese patients with normal basal metabolic rates, the ulcer was attributable to chronic gluttony.

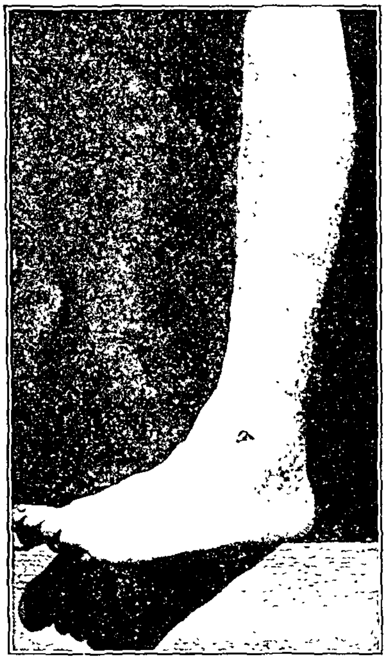

Fig. 8.—Syphilitic ulcer.

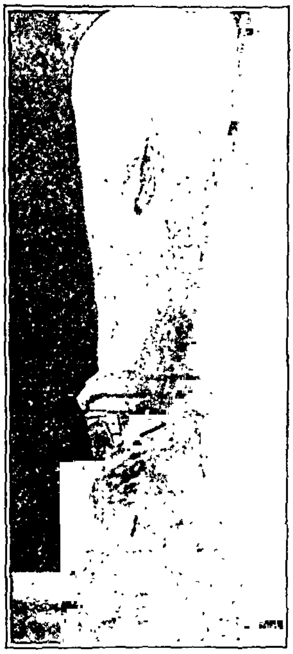

Fig. 9.—Wassermann negative ulcer (before treatment).

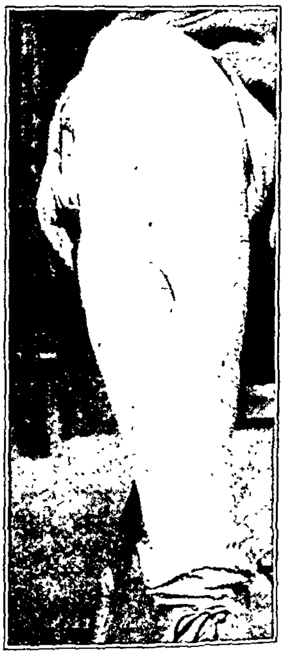

Fig. 10.—Wassermann negative ulcer (after treatment).

*Pernicious Anemia.*—In this case pernicious anemia was basic, complicated with blastomycosis:

A pedler, aged 65, had a raised ulcer of the lower leg as large as two palms, which was clinically blastomycosis. The blood hemoglobin was 21 (Sahli). The color index was 1.4 and the blood smear classic for pernicious anemia.

*Secondary Anemias.*—It is known that primary anemias cause leg ulcer; it is known that a local anemia due to arteriosclerosis of the leg causes leg ulcer; it is therefore not surprising to find profound secondary anemia as the cause of seven cases of leg ulcer in this series. The hemoglobin readings respectively were 45, 55, 45, 47, 56 and 40. These anemias cannot be diagnosed merely by looking for a pale skin; the patient with a hemoglobin of 47 had a natural pink appearance of the skin.

A housewife had a large leg ulcer for which an eminent physician suggested Bazin's erythema induratum (tuberculosis) as a diagnosis. When the hemoglobin was taken it proved to be 55 per cent. The patient's mouth contained foul tooth snags. Treatment consisting of tooth extraction and the daily adminis-

A housewife, aged 57, complained of painful shallow ulcers on the anterior aspects of both legs, surrounded by a broader area of erythema. This area discharged copious serous fluid. There was a burning pain which kept her awake at night, although she felt sleepy all the time. She was enormously obese, but the basal metabolic rate was within normal limits.

A diagnosis was made of gluttony ulcer. She was placed on a diet of 1,000 calories a day. In three weeks she lost 14 pounds (6.4 Kg.) and the ulcers, with the dermatitis, were healed.

### MALNUTRITION ULCERS

In at least one patient, lack of nourishment caused failure of the ulcer to heal:

A Negro "patent medicine" peddler, aged 39, complained of two enormous foul smelling ulcers of the leg. The Wassermann reaction had at one time been positive, but for two and one-half years he had been under intensive treatment; it had been negative for some time, and he had recently been discharged by a clinic for syphilitic patients as cured. The ulcer was no better. The hospital records showed 213 dressings with ointments without improvement. The patient was 71 inches (180 cm.) tall and weighed 134 pounds (61 Kg.), showing a deviation from normal of minus 53 pounds (24 Kg.).

This ulcer was possibly syphilitic at its inception, but the syphilis was no longer active. The ulcer continued because the patient was so undernourished that he lacked resistance to throw off the chronic secondary infection. He was urged to eat eggs, cream, milk and beef steak. He has since been gaining steadily in weight, and the ulcer is healing *pari passu*.

Vitamin deficiency must be considered in some of these cases.

### THE WASSERMANN NEGATIVE ULCER

The diagnosis of the syphilitic leg ulcer may present extreme difficulty.

Clinically, the diagnosis may be difficult. Syphilologists have good reason to disagree as to whether a given leg ulcer is clinically syphilitic. Of course, when an ulcer is deeply punched out, with an irregular border, situated on the lateral aspect of the leg not far below the knee, with no pain until secondary infection sets in, the diagnosis is fairly clear. Frequently, however, I have found ulcers in various locations on the leg without the typical syphilitic configuration, painful from the start, and these healed rapidly under antisyphilitic treatment.

Roentgenologically, the diagnosis is difficult. Roentgen study of the tibia and fibula is occasionally conclusive but is usually inconclusive and often misleading. Roentgenologists both in this country and in Europe[9] are in disagreement as to what constitutes roentgenologic evidence of syphilitic or nonsyphilitic periostitis. Many nonsyphilitic leg ulcers, indeed, most varicose ulcers of long standing, show extensive periostitis, not merely under the ulcer but along the whole shaft of the tibia, suggesting resemblance to the saber-shaped tibia.[10]

Serologically the problem is baffling. It must be remembered that in these cases a negative Wassermann reaction means nothing. It will be observed that in seven out of seventeen on the list the Wassermann reaction was negative. I have found little help from the provocative Wassermann test. On the other hand, I have had two patients with a positive Wassermann reaction in whom removal of other causes, such as invisible varicose veins, brought about the cure.

One test in the clinically doubtful case is simple and inexpensive and has thus far seemed reliable. A therapeutic test of injections of bismuth compounds or of intramuscular injections of milk, and sodium iodide by mouth is ordered. The syphilitic ulcers show marked improvement usually after the second or third injection of the bismuth preparations.

The arsphenamines cannot be trusted to cure this type of tertiary syphilis. Every leg ulcer not explicable on other grounds should receive a therapeutic test of injection of a bismuth preparation, and iodides.

Does a rapid cure under bismuth and iodides prove that the ulcer was syphilitic? With the knowledge of the relation of iodides to the thyroid and of the thyroid to the skin, it is possible to postulate that the cure may be related to the action of the iodides on the thyroid. It is possible also to postulate some nonspecific action of bismuth stimulating the system to healing of the ulcer.

For these reasons a theoretical doubt may be raised as to whether the mere fact of healing under bismuth and iodides proves an ulcer to be syphilitic. I have therefore called these ulcers Wassermann negative ulcers rather than syphilitic ulcers. Practically, however, I find that of the Wassermann negative patients with leg ulcers healed under this test, searching questions into their histories bring out information as to a miscarriage, a chancre, or a positive Wassermann reaction years ago.

A man, aged 59, a cook, had a painful old osteomyelitis wound on the middle of the anterior aspect of the right tibia measuring 5 cm. by 1 cm. A roentgenogram showed no present signs of infection in the bone itself. His endocrine history was unusually interesting and was written up by Llewellys Barker[11] and was published in 1915. He had had a decompression operation on the brain some years before.

Three blood Wassermann tests were negative. The Kahn reaction was plus minus. The patient said that years before a Wassermann reaction had been positive, but this had been regarded as a mistake, for several Wassermann tests taken *immediately afterward* were negative. He scorned the suggestion that his ulcer could be syphilitic and demanded a skin graft operation.

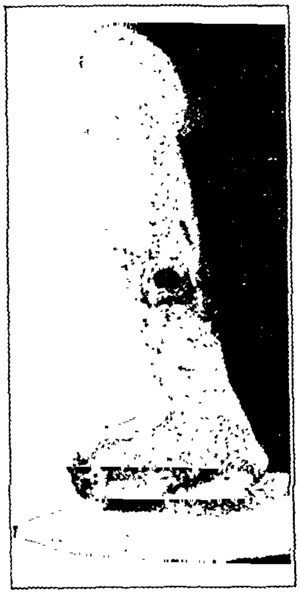

Fig. 11.—Blastomycosis.

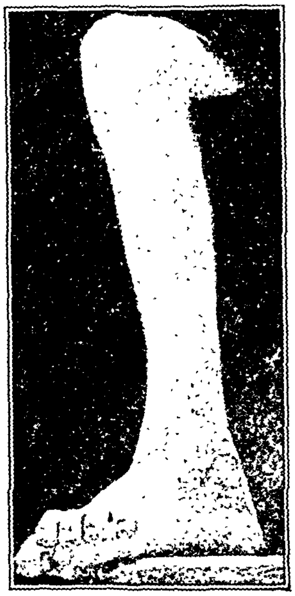

Fig. 12.—Iodermia.

The diagnosis made was Wassermann negative congenital syphilis. With no local treatment and under treatment by bismuth compounds and iodides the ulcer healed as by magic. For six months there has been no sign of any recurrence.

### TUBERCULOUS ULCERS

Leg ulcers due to erythema induratum (Bazin's disease) were formerly thought to be tuberculids, i. e., lesions caused by the toxins of tuberculosis elsewhere in the body; but they are now acknowledged to be true tuberculomas caused by the local presence of the tubercle bacillus. The onset is usually in young persons. The ulcers are preceded by painless nodules which break down, leaving small deep ulcers with undermined margins with a gray base. As contrasted with syphilis, the ulcers are usually bilateral and do not heal under antisyphilitic treatment. Sometimes biopsy material, if ground up and injected into a guinea-pig, will cause tuberculosis in the guinea-pig. There was probably one such case in this series. These ulcers have been described in detail by Hart-Drant.[12]

### MYCOTIC ULCERS

The mycotic ulcers characteristically have a hypertrophic raised border with purulent matter easily expressed from small sinuses. The border does not usually have the firmness of an epithelioma. Mycotic forms may or may not be demonstrated by biopsy and culture. They have recently had a detailed description by Jacobson.[13]

### DRUG ULCERS

Ulcers due to bromide medication or to phenobarbital medication have been reported.[14]

There was only one drug ulcer in this series and this was due to iodides given in the treatment of a syphilitic lesion of the foot. The diagnosis was not difficult because in this case similar crusted ulcers appeared on the neck. Drug ulcers, however, may be limited to the leg and be unilateral, single, large and deep.

### NEUROTROPHIC ULCERS: TWO TYPES

If research is to make progress, it must distinguish sharply between two contrasting types of neurotrophic leg ulcer.

*Anesthetic Type.*—This type is associated with anesthesia of the ulcer; perforating ulcers of the foot are in this class. This type is the result of nerve lesions due to tabes, syringomyelia, beriberi, diabetes and leprosy.[15]

A former boiler maker, aged 61, complained of an ulcer of ten years' duration. There were a few varicose veins. There was much edema of the foot and some of the calf above the ulcer. The ulcer was deep, measuring 6 cm. by 8 cm. on the anterior aspect of the middle of the lower right leg. The knee joint was very loose and allowed loose lateral motion. The patellars reacted. The Romberg sign was strongly positive. The blood Wassermann reaction was 4 plus. The ulcer was obviously tabetic and had not responded to ordinary antisyphilitic treatment.

*Hyperesthetic Type.*—The other type is associated not with anesthesia but with exquisite pain and tenderness in the region of the ulcer. This is the irritable ulcer of the malleolus, described by Corlette.[16]

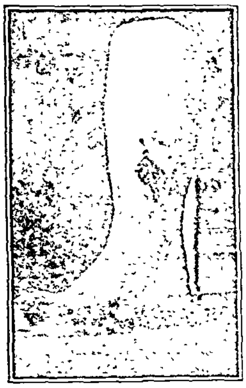

Fig. 13.—Neurotrophic ulcer (anesthetic type).

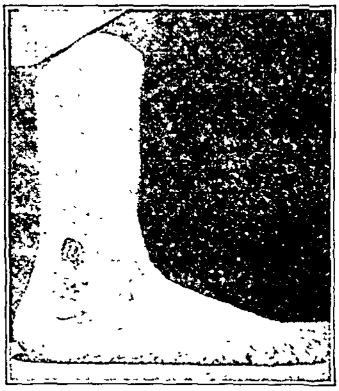

Fig. 14.—Neurotrophic ulcer (hyperesthetic type).

I have seen only one such ulcer and seriously question whether all cases reported by Corlette are due to nerve lesions. In cases which I at first found to meet Corlette's description, further study demonstrated causes other than nerve lesions which, when treated, allowed the ulcer to heal.

In the case of Mrs. U. B., one ulcer occurred just above the external malleolus, of five years' duration, and one just above the internal malleolus, of one year's duration. She was anemic, but a marked ocular nystagmus pointed to a nerve lesion. Neurologic examination demonstrated an upper neurone lesion. Instead of making the subcutaneous section of the nerves as recommended by Corlette, I injected diluted quinine-urethane subcutaneously as a permanent anesthetic. This brought complete relief from pain in both ulcers and rapid healing in one of them. The unhealed ulcer is improving.

### MALIGNANT CONDITIONS

A malignant condition in a leg ulcer is to be suspected whenever there is a hard, rolled border which bleeds easily. White and Weidman[17] have recently issued a warning against the diagnosis of carcinomatous ulcer of the leg on insufficient histologic evidence. I fear, however, that if one waits until, as they suggest, the cells have penetrated to the level of the sweat glands, one may wait too long. In this case, sections through the inguinal lymph glands already showed metastases. The ulcer shown in figure 15 had begun four years before as a small pustule. It had caused very little pain. It had a firm rolled border, and bled easily. The inguinal lymph glands were enlarged.

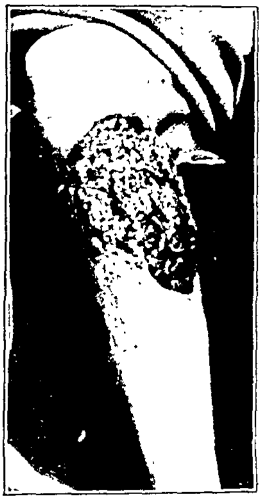

Fig. 15.—Carcinoma

Dr. H. P. Jacobson took the biopsy and I saw the case as surgical consultant. A microscopic examination showed that it was a basal cell carcinoma of the adenocystic type. It was found both in the ulcer and in the inguinal lymph glands. This carcinoma had been unrecognized by a number of eminent clinicians and had been treated with ointments.

### SUMMARY

Several causes of chronic leg ulcer are not commonly recognized. The leg ulcer due to varicose veins which are not visible, but buried as a stagnant lake of blood deeper in the tissues and demonstrable by roentgenograms with iopax, is one of the most common of these unrecognized causes.

**Normal Range of Basal Metabolism.**—Any definition of "normal range of basal metabolism" is necessarily arbitrary. There is, of course, a gradual diminution in the likelihood that a given person's metabolism is normal, as our measurement shows it to deviate from the zero point. If 7 is accepted as a typical coefficient of variation of the basal metabolic rates of normal persons tested with careful technic, the probability is that a normal person will deviate any given distance in a given direction from the mean. It is obvious that normal range of 10 per cent is dangerously small, as two normal persons in thirteen may be expected to fall outside the normal range, one at either end.—Jenkins, R. L.: Basal Metabolism, *Arch. Int. Med.* 49:181 (Feb.) 1932.

# ARTHRITIS OF THE CERVICAL SPINE

## SOME NEUROLOGIC MANIFESTATIONS

J. DEWEY BISGARD, M.D.
CHICAGO

Investigation in recent years has established the fact that radiculitis of arthritic origin, or funiculitis (Sicard's[1] terminology), is a common manifestation of vertebral arthritis of the cervical as well as the thoracic, lumbar and sacral spinal segments. Symptoms directly referable to the local disease are usually minimal and frequently absent. In contrast, the magnitude of the nerve root symptoms and the remoteness of their distribution often give rise to such varied, illusive and bizarre clinical pictures that it is not unusual to observe failures to recognize the underlying pathologic process. Consequently, such symptoms are not infrequently classified as clinical entities such as neuritis and neuralgia. That the pain may simulate that arising from visceral disease has been stressed by Oppenheim.[2] In point, a case history compatible with angina pectoris will be described subsequently.

Contributing to the confusion in diagnosis is the fact that the motor and sympathetic as well as the sensory components of the nerve roots are not infrequently involved and, similarly, may reflect evidence both of interference in conduction and of stimulation. The meager references to these phenomena in the literature led to the investigation herewith reported.

Arthritis of the spine may be a part of a generalized process including one or more joints of the extremities, or the process may be limited to the vertebral column. Likewise, the spinal involvement may be restricted to certain segments such as the cervical or lumbar spine and not infrequently only to two or three vertebrae. Of interest is the localization of the process to the bodies of the fifth, sixth and seventh vertebrae in the majority of cases of cervical arthritis. To this observation figures 1 and 2 bear witness. The assumption that these segments suffer greater functional trauma would favor such localization.

A conception of the frequent occurrence of arthritis of the spine in persons past middle life can be gained from a study reported by Garvin.[3] At the Mayo Clinic during the year 1925, roentgenograms of the urinary tract were made of 2,090 patients over 50 years of age, and with few exceptions these examinations had no reference to spinal disease. The incidental observations of frequent radiographic evidence of vertebral arthritis led to an investigation of these patients. It was found that 58 per cent of the series presented roentgen evidence of hypertrophic arthritis of the spine—men 67 per cent and women 40 per cent. From this group detailed analyses were made of 500 cases selected at random, and it was found that 74 per cent of the men and 61.5 per cent of the women with hypertrophic arthritis of the spine had no accompanying complaints of rheumatism or neuromuscular pains. Goldthwait[4] and Baber[5] have commented on the slightness or absence of symptoms in the presence of extensive pathologic changes. Similarly, Nissen[6] has observed its presence in patients for years without symptoms until precipitated by trauma, strain and fatigue.

The pathology of ostearthritis of the spine has been described by Goldthwait[4] and others. It consists of a proliferation of the borders of the articular cartilage with subsequent ossification and formation of osteophytes (lipping, spurs). As the process progresses, it extends into the ligamentous structures, and the newly formed "spurs" or "beaks" may fuse to form bridges, which ankylose adjacent vertebrae. The pathologic changes in the vertebral bodies are well illustrated in figure 1. Radicular involvement, funiculitis, results from the associated inflammatory reaction with irritation of, or pressure on, the nerve roots in the intervertebral foramina.

In outlining the symptomatology of arthritis of the cervical spine, reference will be made to an analysis of sixty cases observed at the University of Chicago Clinics. During a period of four years (1927 to 1932) there were studied in the clinics 386 cases of chronic arthritis of undetermined etiology classified as proliferative (rheumatoid arthritis) and degenerative (ostearthritis). Of this group, sixty cases presented evidence of arthritis of the cervical spine as a localized entity or as part of a more or less generalized process involving one or more joints remote to the spine.

### I. HEADACHES

Thirty-one patients complained of headaches either alone or associated with other symptoms. They were occipital or suboccipital in location with, in some cases, radiation into the neck or up over the head. In many cases they became worse in damp and cold weather and were aggravated by bending or twisting the head and by jarring in walking, coughing or sneezing. Frequently relief was obtained by supporting the head with the hands, by lying down, or by the application of heat.

Holbrook[7] has stressed the necessity of a consideration of the cervical spine in the investigation of every patient complaining of headaches, and states that headaches from cervical arthritis may be sufficiently persistent and severe to suggest the possibility of a brain tumor. The following is an illustrative case:

CASE 1.—J. M., a Scotchman, aged 67, seen Sept. 13, 1930, complained of severe suboccipital headaches of one and one-half years' duration, coming on at first only in damp weather. For a year they had been almost constant when he moved about. He had no headache on awakening in the morning, and relief was always obtained by sitting quiet or lying down. The headache was promptly precipitated and always aggravated by any sudden motion of the head or by rubbing his hands over his head in washing his face.

Examination revealed carious teeth, pyorrhea, and pulmonary emphysema. There were no areas of tenderness of the head or neck, and there was no crepitation or restriction of motion of the neck. Percussion and jarring of the head or neck caused pain. The routine studies of the blood and the urine, including the Wassermann reaction, were negative; the blood pressure was 132 systolic and 90 diastolic. Roentgenograms of the chest were negative; those of the cervical spine showed narrowing of the sixth intervertebral space and lipping of bodies 5, 6 and 7.

The diagnosis was ostearthritis of the cervical spine with radiculitis.

### II. SYMPTOMS LOCALIZED TO THE NECK

Pain, tenderness, stiffness, ankylosis and crepitation, localized to the neck, were observed in thirty-eight cases

as local manifestations alone or in conjunction with remote root symptoms. Tenderness over the spinous processes, drawing sensations, and a sense of fatigue in the neck and shoulders were common complaints. Only four cases, one of Still's disease, two of advanced arthritis deformans and one of rhizomelic spondylosis, presented marked limitation of motion.

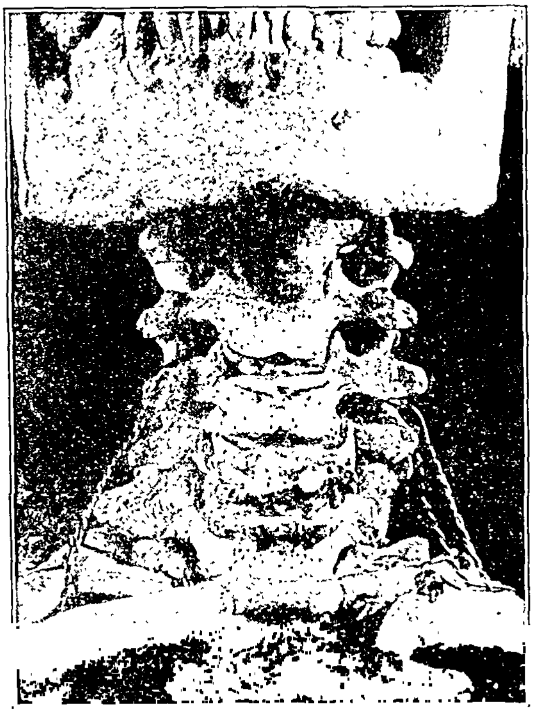

Fig. 1.—The cervical spine of a skeleton illustrating bone proliferation along the upper and lower margins of the body of the fifth and the margins of the adjacent articular surfaces of the fourth and sixth vertebrae.

Cases 2 and 3 illustrate local symptoms:

Case 2.—B. J., a white woman, aged 43 seen, Dec. 18, 1930, gave an indefinite family history of "rheumatism" (maternal). The past history contributed nothing of importance; she stated that she had never had venereal infection. She had three children, living and well, and had had no miscarriages or stillbirths.

Relief was sought from a constant pain of two years' duration in the back of the neck. It extended the full length of the cervical spine and was never sharp but it frequently disturbed her sleep. Some relief was obtained by lying on her face. The course had been punctuated by frequent exacerbations and for two weeks preceding admission the carpophalangeal joints of both hands had become painful, swollen and stiff.

Periodically for ten years there had been similar involvement of the fingers and pain in both hips.

There was tenderness to pressure over the spinous processes of the sixth and seventh cervical vertebrae and some tenderness, swelling and pain on motion of the right first metacarpophalangeal joint. There were no Heberden's nodes, and all joints, including the neck and the hips, had painless normal range of motion. The blood Wassermann and Kahn tests were moderately positive but the spinal fluid was negative. Other studies of the blood and urine were negative.

The roentgenograms of the cervical spine displayed moderate lipping of the anterior margins of the bodies and in the anteroposterior view dense sclerosis of the articular facets.

The diagnosis was (1) ostearthritis of the cervical spine, both hip and phalangeal joints, with radiculitis, and (2) syphilis.

Case 3.—F. S., a man, aged 45, seen, Oct. 7, 1931, with irrelevant family and past histories, complained of an annoying sensation of pain and fatigue of three years' duration in the back of the neck, extending down between the shoulder blades. The pain was constant and not severe but made worse with exposure to cold. The patient felt conscious of an effort to support his head, a "tired feeling" in the neck, relieved by resting his head in his hands. On rotating the head he frequently experienced a sense of crepitation and a sound of creaking. There was no history of antecedent trauma.

Examination confirmed the patient's observation of crepitation, but there was no limitation of motion and no tenderness or pain on motion. The blood pressure was 122 systolic and 86 diastolic. The routine studies of blood and urine, including the Wassermann and Kahn tests, were negative.

A roentgenogram showed some proliferative ostearthritis of the fifth and sixth cervical vertebrae.

The diagnosis was ostearthritis of the cervical spine with radiculitis.

### III. PAIN RADIATING INTO THE ARMS

Eight patients complained of "neuritis" in the shoulders and arms. The pain was usually described as quite severe, often dull and usually paroxysmal, but occasionally constant. Except in one case with a typical ulnar nerve distribution the pain did not have a definite segmental arrangement and in most instances was not well defined. In five cases it was unilateral; in three, bilateral. Its extension varied from the shoulder to the tips of the fingers. Frequently there was an associated sense of weakness and awkwardness in motion of the fingers and arms and, in most cases, numbness and paresthesia. The following case histories are illustrative:

Case 4.—G. L., a man, aged 58, seen, May 4, 1931, supported by crutches and long leg braces, gave a history of paralysis of both lower extremities, persisting since its onset when he was 14 months of age. He had never walked without the aid of crutches. Seven months before he was seen at the clinics, pain developed in the left shoulder and had progressed down the arm, occasionally radiating to all the finger tips. The pain seemed to be located deep in the arm, was frequently severe, and was always worse in cold and damp weather. He had noticed no limitation of motion and no loss of strength, and motion did not influence the pain. There had been no numbness nor paresthesia.

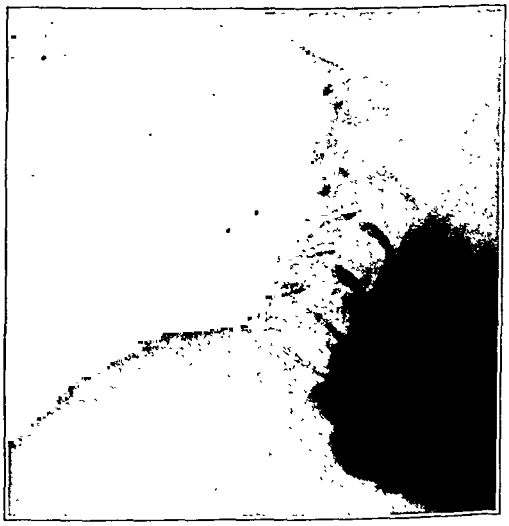

Fig. 2 (case 6).—Rather extensive lipping of the contiguous anterior margins of the bodies of the fifth, sixth and seventh cervical vertebrae.

Both lower extremities were almost completely flail but the abdominal and back muscles had normal strength. The musculature of the upper extremities appeared to be overdeveloped and there was no objective evidence of disturbed function of the motor or sensory nerves. Percussion of the spinous processes of the fifth and sixth cervical vertebrae elicited pain in the neck, but motions of the neck were unrestricted and painless.

Studies of the blood and urine, including the Wassermann and Kahn reactions, were negative.

Roentgen examination revealed normal bony components of the shoulder girdle and no evidence of cervical rib. There was proliferation (ostearthritis) of the anterior margins of the third to sixth cervical vertebrae inclusive, and calcification of the anterior ligaments.

The diagnosis was (1) ostearthritis of the cervical spine with radiculitis, and (2) residual paralysis of anterior poliomyelitis.

Case 5.—P. W., a man, aged 55, seen, April 25, 1930, had had typhoid at the age of 16. For fourteen years he had had frontal headaches and "hay fever" with occasional attacks of asthma. For five years he had had "rheumatism" in the right knee, and five years before admission he was confined to his bed for a week with concussion of the brain as a result of a blow on the head from a falling block.

For one year he had suffered from pain in the neck, radiating down between the shoulders and out into both arms as far as the elbows *(distribution not well defined)*. It became worse in damp weather and often disturbed his sleep. There was an associated sense of stiffness and creaking on motion.

The examination, including dental roentgenograms, examination of the urine and blood, and Wassermann tests, was negative except for a palpable grating sensation of the cervical spine on motion. There was no tenderness or limitation of motion and no evidence of disturbance of sensory or motor function.

Roentgenograms of the cervical spine showed lipping of the bodies of the fifth and sixth vertebrae. The sinuses were clear, and there was no evidence of cervical rib.

The diagnosis was ostearthritis of the knee and cervical spine with radiculitis.

Of interest is the presentation of a definite history of injury.

Case 6.—C. C. a woman, aged 47, seen, Aug. 2, 1929, with moderate hypertension (blood pressure 154 systolic and 104 diastolic) and a diagnosis of chronic functional colitis, complained of sharp pain of one year's duration in the neck on top of and between the shoulders, with radiation into the epigastrium. For six weeks following the onset of these symptoms she had had severe hiccups. They were quite constant with only brief periods of relief obtained occasionally by lying quiet and with pressure applied bilaterally over the anterolateral aspects of the neck. For two weeks before admission, rather severe shooting pains had periodically radiated down both arms and into the fingers.

There was definite tenderness to percussion of the lower cervical and lower thoracic spinal segments. Tenderness could also be elicited in the ninth and tenth intercostal spaces on the left side and at the base of the neck.

The laboratory studies were negative.

The roentgenograms (fig. 2) of the spine showed marked lipping of the anterior margins of the bodies of the fifth, sixth and seventh cervical vertebrae and of the articulating borders of the bodies of the eighth, ninth and tenth thoracic vertebrae. There was no evidence of cervical rib.

The diagnosis was ostearthritis of the cervical and dorsal spine with radiculitis. . .

The symptoms giving rise to the diagnosis of functional colitis and questionable gallbladder disease in this case were no doubt radicular in origin from the arthritis of the thoracic spine. The possibility of involvement of the phrenic nerve is discussed elsewhere.

### IV. NUMBNESS AND PARESTHESIA OF THE ARMS

Sensory disturbances were prominent features in five cases and were noted in four additional cases. The topography of these sensations and the areas of diminished sensations were usually diffuse and in only two instances sufficiently well defined to correspond to nerve root or trunk distribution. These two cases presented objective evidence of sensory nerve involvement capable of nerve root localization. The patients stated that their arms or hands felt as though they were asleep, or they complained of tingling (pins and needles), burning, crawling (of bugs) and stinging sensations. Two illustrative cases are presented:

Case 7.—A woman, aged 54, seen, May 26, 1931, sought relief of numbness and tingling of the arms. The onset occurred six weeks previously with these sensations in the second and third fingers of the left hand and in a few days extended up the medial volar surface of the forearm to 3 inches above the elbow. Three days later the right hand and forearm became identically involved. Subsequently there developed sensations of ants creeping under the skin and dull boring pain which disturbed her sleep. For a few days she experienced sudden quick momentary throbs in both hands, and cramps in the arms.

Slight hypesthesia was demonstrated over the volar surfaces on the medial aspects of both forearms, more marked on the left side, suggesting irritation of the eighth cervical and first thoracic roots bilaterally.

The dental consultant reported periapical lesions of two teeth. The urine, blood, and Wassermann and Kahn tests were negative.

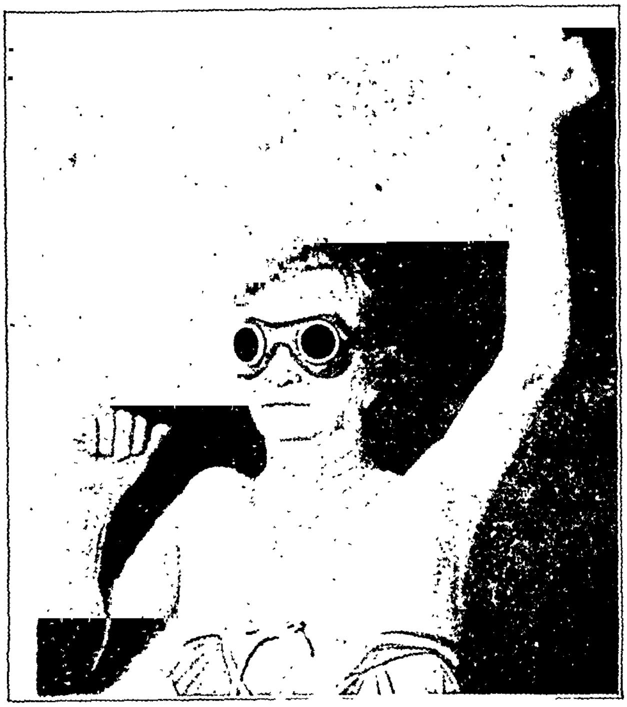

Fig. 3 (case 9).—Paralysis of the deltoid and weakness of the biceps and triceps of the right arm. Wasting of the deltoid and inability to abduct the arm are noticeable.

Roentgenograms demonstrated lipping of ostearthritis of the bodies of the fifth, sixth and seventh cervical vertebrae. There was no evidence of cervical rib.

The diagnosis was ostearthritis of the cervical spine with radiculitis.

Case 8.—E. A., a man, aged 66, seen, Oct. 16, 1931, had had "catarrh" and occasional sore throat for many years and pain from renal calculi until removal twelve years ago. Ten years before admission he twisted his neck severely but was not incapacitated.

For five years his neck had felt stiff and for two and one-half years there had been a constant dull and an occasional sharp pain in the right shoulder and arm. One and one-half years later, the same symptoms appeared in the left shoulder and arm, and diffuse numbness and weakness subsequently developed in both arms. These symptoms were exaggerated by cold and "changeable" weather, were worse in the morning, and were relieved by lying down.

There was some limitation of motion of the neck and tenderness on palpation of the cervical spine.

The blood, urine, Wassermann and Kahn tests were negative; the blood pressure was 128 systolic and 90 diastolic.

Roentgenograms demonstrated some loss of cartilage space (sixth) and lipping and fusion of the anterior margins of the bodies of the sixth and seventh cervical vertebrae.

The diagnosis was ostearthritis of the cervical spine with radiculitis.

It should be noted that an indefinite history of injury was given.

### V. EFFERENT (MOTOR) DISTURBANCES

Of the sixty cases, there were four with definite evidence of motor nerve involvement and a large group in which some disturbance could be assumed. Associated with the sensory symptoms in the majority of cases, there was a complaint of weakness or difficulty in coordination of certain muscle groups or of the entire extremity. Objective confirmations of these observations were not infrequent. Definite atrophy, generalized or localized to certain muscles, was noted in several cases, but obviously this is difficult to differentiate from atrophy of disuse resulting from the pain. Wasting of the thenar and hypothenar eminences was observed in several cases. Case 9 will serve to illustrate the paralytic phenomena:

Case 9 (fig. 3).—A. F., a woman, aged 51, seen, Oct. 30, 1931, had always been perfectly well until one year before admission, when she suddenly became aware of numbness and tingling in the fingers and hypothenar eminence of the right hand. This persisted for a week, and there were no further symptoms until three months before admission, when she noticed the development of a progressive weakness in the right arm and complete inability to abduct the arm. There was no associated pain or other sensory disturbance.

Examination revealed slight irregularity of the pupils but normal reflexes except for the right arm. The blood pressure was 102 systolic and 70 diastolic, and the arteries were not sclerosed.

The right arm showed some atrophy throughout with rather marked wasting of the deltoid. There was almost complete loss of function of the deltoid, marked weakness of the triceps and biceps, absence of right biceps and triceps reflexes, and a questionable hypalgesia in the right axillary nerve distribution. These observations were interpreted to be the result of involvement of the fifth and sixth cervical roots. No tenderness or limitation of motion could be demonstrated in the right shoulder or cervical spine.

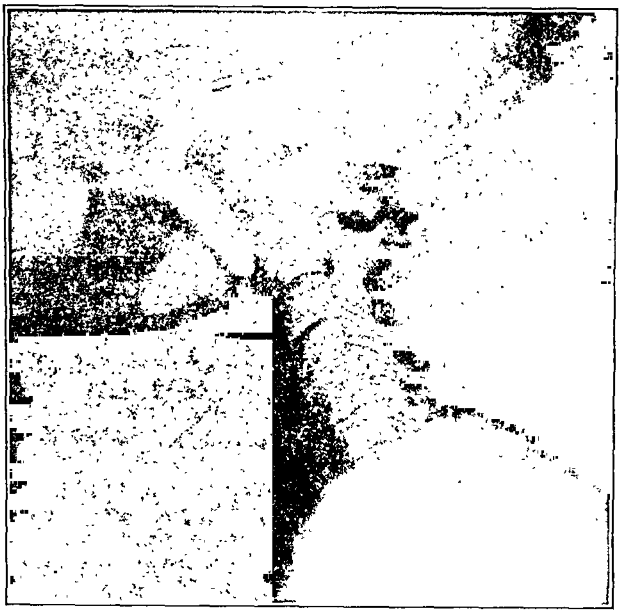

Fig. 4 (case 9).—Involvement of the bodies of the fifth, sixth and seventh cervical vertebrae. Radiculitis of the fifth and sixth cervical roots.

The laboratory examinations of the cerebrospinal fluid, the urine and the blood gave normal results, and the blood Wassermann and Kahn reactions were negative.

Roentgenograms of the chest and right shoulder were negative. There was no evidence of cervical rib. Those of the cervical spine showed narrowing of the fifth intervertebral space and lipping of the anterior margins of the bodies of the fifth and sixth cervical vertebrae.

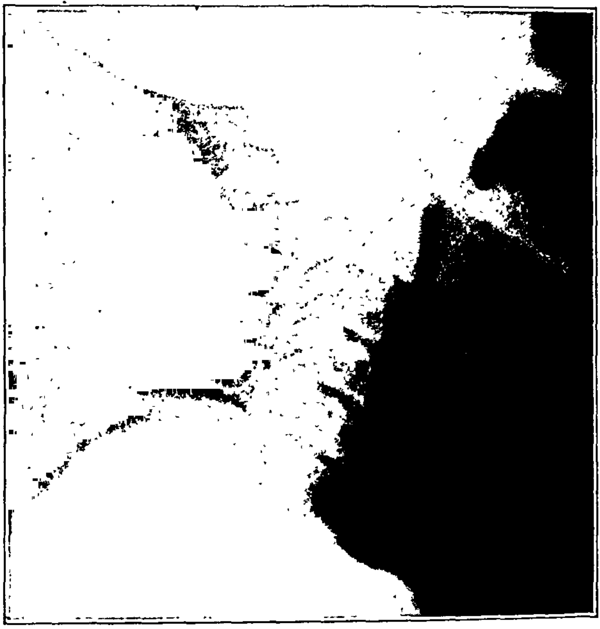

Fig. 5 (case 10).—Rather extensive ostearthritis of the entire cervical spine and calcification of the anterior group of ligaments.

The diagnosis was ostearthritis of the cervical spine with radiculitis (motor paralysis).

The motor symptoms may reflect evidence of irritation and stimulation of the root fibers, such as twitchings and continuous or spasmodic contractures. Case 10, a spasmodic torticollis, represents this type of disturbance. One patient in the series had flexion contractures of the third and fourth fingers, and three patients gave vague histories of cramps and transitory twitchings, one of the shoulder and two of the forearm and fingers. Lasserre[8] reported a case of cervical arthritis with spastic torticollis which was irreducible and persisted for three weeks.

Radiculitis from cervical arthritis may reflect involvement of the cervical sympathetic nerve fibers. Wagenhals[9] reported a case with Horner's syndrome on one side.

One case of this series gave a history of hiccups of six weeks' duration coming on simultaneously with other symptoms of arthritis of the cervical spine. It is possible that it resulted from radiculitis of roots from which the phrenic nerve derives its fibers (case 6).

Case 10.—B. T., a housewife, aged 56, seen, Sept. 22, 1930, had had attacks for ten years of acute pain in the precordium that would last for only a few minutes and came on several times each day. For five years she had had "rheumatism" in both arms and in the back of the neck, characterized by dull and shooting pain and limitation of motion. The pain in the neck radiated down between the shoulder blades and into the chest.

Five years before admission there developed periodic attacks of spasmodic jerking of the face to the right and the head toward the left shoulder, exaggerated with excitement and quieted with rest.

---

[8] Lasserre, C.: Cervical Arthritis in Rheumatism, Arch. franco-belges de chir. 32: 604 (July) 1930.

[9] Wagenhals, F. S.: Neurological Disturbances Associated with Hypertrophic Arthritis of the Spine, Ohio State M. J. 25: 31 (Jan.) 1929.

The patient, a slender woman, was made conspicuous by frequent spasmodic contractures of the left sternocleidomastoid muscle drawing the head toward the left shoulder and pointing the chin to the right. With each spasm the left shoulder rose, and contracture of muscles of the left shoulder girdle and of the left sternocleidomastoid muscles could be palpated. No tenderness or limitation of motion in the cervical spine could be elicited. Pressure over the third, fourth and fifth thoracic vertebrae caused discomfort.

The blood pressure was 190 systolic and 110 diastolic. The Wassermann and Kahn tests and the urine and routine blood examinations were negative. Electrocardiography showed a slight tendency to left ventricular preponderance.

The roentgenograms revealed lipping of the anterior borders of the bodies of the fifth, sixth and seventh cervical vertebrae (fig. 5) and no evidence of cervical rib.

The diagnosis was (1) ostearthritis of the cervical and thoracic spine with radiculitis (spasmodic torticollis) and (2) hypertension.

The differential diagnosis of arthritis of the cervical spine involves a consideration of a large group of intrinsic lesions of the central and peripheral nervous system, certain general and visceral disease processes and such conditions as arthritis of the shoulder and other joints of the arm, subdeltoid bursitis, cervical rib, and various lesions of the cervical vertebrae. The latter group includes tuberculosis (cervical Pott's disease), fractures, dislocations, new growths (primary or metastatic), osteomalacia, osteomyelitis and actinomycosis. Added to other uncertain factors in diagnosis is the frequent occurrence of extensive vertebral arthritis without symptoms in persons past middle life.

The present methods of treatment of radiculitis resulting from cervical arthritis are generally conceded to be very unsatisfactory. The therapeutic measures that are applicable to arthritis in general are a benefit. Considerable relief of symptoms is obtained by immobilization of the cervical spine for several weeks in a Thomas collar with short periods of stretching (traction) each day. I [10] recently described a device which provides an effective method of applying these principles.

Roentgen irradiation of the spine in repeated small doses has proved definitely beneficial in many cases. Pfender [11] has reported some excellent results and attributes them to the decompression resulting from the action of the rays on the connective tissue surrounding the nerve roots in the intervertebral foramina.

Special indications arise which demand special forms of treatment, such as the prevention of overstretching of paralyzed muscles and of contracture deformation.

### CONCLUSIONS

1. Symptoms of sixty cases of arthritis of the cervical spine were analyzed. They represent 15 per cent of all cases (386) of arthritis of undetermined etiology studied over a period of four years at the University of Chicago Clinics.

2. Ten illustrative case histories emphasize the complete or relative silence of subjective and objective evidence of the primary lesions of vertebral arthritis as compared to the major rôles played by the nerve roots which are secondarily involved. In general, it may be said that arthritis of the cervical spine manifests itself by signs and symptoms remote in respect to the spine.

3. Radiculitis may involve any group of nerve fibers contained in a nerve root; that is, somatic and sympathetic motor and sensory, and the symptoms may reflect evidence of irritation or complete or partial loss of function.

4. The symptoms are frequently elusive and may simulate many visceral, cerebrospinal, local and general disease entities.

950 East Fifty-Ninth Street.

# NONTUBERCULOUS ARTHRITIS

## A DESCRIPTIVE CLASSIFICATION

M. J. SHAPIRO, M.D.
MINNEAPOLIS

In order to appreciate the classification of chronic arthritis proposed by the American Committee for the Control of Rheumatism, one has to be familiar with the work of Nichols and Richardson, on which the classification is based. Their treatise [1] on chronic joint disease, published over twenty years ago, is possibly the most extensive study of this topic ever made and is of fundamental importance in that it showed that all types of chronic nontuberculous arthritis tend to fall into two main groups. Richardson,[2] in 1905, reported on the clinical manifestations of seventy-five cases of arthritis. He divided these cases into two clinical groups which he labeled group I and group II. Nichols and Richardson, after spending eight years in histologic studies of sixty-five cases, found that the cases again fell into two main groups, which they called proliferative and degenerative, and that clinical group I corresponded to the proliferative and group II to the degenerative type. The authors stressed the point that the cases of the two groups were not necessarily of different etiology; from this point of view there was considerable overlapping. Nichols and Richardson emphasized that a certain pathologic alteration of a joint may be the result of a variety of irritants or agents, and a given irritant or agent may produce a variety of pathologic changes. Trauma, acute suppurative infection, gonorrhea, syphilis, probably faulty metabolism and probably also a variety of other factors may induce primary proliferation of the synovial membrane, while old age, trauma, dislocations, bone tumor, gout, diseases of the central nervous system and other causes may lead to primary degeneration of the cartilage. Nichols and Richardson thus included under proliferative arthritis various types of specific and nonspecific arthritides. That a variety of causes may produce the same gross and histologic changes and one etiologic factor result in a variety of pathologic pictures, this clear realization of Nichols and Richardson, is important to bear in mind. Many writers have adopted a different usage, applying the term "proliferative arthritis" to designate nonspecific disease only and describing all specific infections separately. Pathologically, Nichols and Richardson did not differentiate a gonorrheal, staphylococcic or streptococcic joint from a nonspecific infectious arthritis; all were proliferative arthritides. Nor were they able to differentiate between a degenerative arthritis secondary to trauma, syphilis or senile changes. The same excellent treatise also brought out the fact that a proliferative arthritis, if it continued sufficiently long, might develop changes characteristic of the degenerative type, particularly osseous hypertrophy. In one and the same patient, at the same time, one may find one joint with typical degenerative changes and another showing definite proliferative changes. Osgood,[3] as well as Strangeways,[4] who spent many years studying chronic arthritis, has pointed out this possibility.

The proliferative process, which was found to be of sufficient importance to form the basis for a classification, commonly begins in the synovial membrane, and it is necessary in the bizarre terminology of arthritis to remember that the term "proliferative" always does or at least always should refer to synovial proliferation. A pannus-like membrane of granulation tissue is the result of the proliferative process; this membrane spreads over the joint cartilage. Wherever the pannus comes in contact with the cartilage, it produces erosion and destruction. At the same time a reaction is stimulated in the perichondrium which starts to proliferate, developing new cartilage and even new bone. Thus several processes are in progress: synovial proliferation, destruction of cartilage, and formation of new cartilage and new bone. There may also be a proliferative process in the subcartilaginous endosteum invading the joint cartilage, which thus is being destroyed both from above and from below. The epiphyseal bone marrow shows an increase in connective tissue and increased vascularity. There may or may not be an epiphyseal diminution of the bone trabeculae. The decrease in epiphyseal bone tissue on the roentgen film gives an atrophic appearance and explains the x-ray name for this type of arthritis: atrophic arthritis. Fibrous adhesions occur early and often become extensive, producing a multiloculated joint cavity. These adhesions cause fixation of the joint, leading to further bone atrophy. In advanced cases the joint may be entirely destroyed and the adjacent bones fused together with a continuous marrow cavity. Subluxations and dislocations are frequent in proliferative arthritis. Effusion into the joint cavity together with articular and periarticular swelling produces the characteristic fusiform joint of this type of arthritis.

Degenerative arthritis is characterized by fibrillation and degeneration of the joint cartilage, especially in its central portion, together with an overgrowth of bone at the edges of the joint. Ankylosis due to adhesions does not occur, but there may be locking of the joint due to exostoses. As the name indicates, this is primarily a senile degenerative process with little evidence of inflammation.

Clinically these types may be differentiated in the manner shown in table 1.

The American Committee for the Control of Rheumatism accepted Nichols and Richardson's classification. The terms proliferative and degenerative are used synonymously with atrophic and hypertrophic and with the English rheumatoid arthritis and ostearthritis.

Proliferative = Atrophic = Rheumatoid
Degenerative = Hypertrophic = Ostearthritis

Against the background of the previous brief discussion the logic in this synonymous usage is easily seen; without it the terminology is confusing.

A review of recent literature indicates that the committee's classification is not being used by all workers in this field. On the contrary, the classifications in common use are as varied and confusing as if the committee had never existed. Most classifications are based on one aspect of the disease only: either the pathologic picture or the roentgenologic characteristics, or sometimes on presumed etiology. Hench,[5] among others, has proposed such an etiologic classification. The fallacy of an etiologic classification has been pointed out by Osgood, Assman[6] and others. While it is agreed that a considerable group of arthritides will prove to be infectious, it cannot be said that this question has been settled. It hardly seems possible at this time to state which types of arthritis are infectious and which are not. Some investigators, Clawson,[7] and Cecil and his co-workers,[8] find a high percentage of positive blood and joint cultures in chronic arthritis, while others, Swift,[9] and Dawson and his co-workers,[10] are unable to corroborate this work. It must not be forgotten that there are considerable data indicating that some arthritides are intimately related with constitutional inferiorities, metabolic disturbances and gastro-intestinal malfunctions, factors the exact importance of which is difficult to determine. By picking out

Table 1.—*Characterization of Proliferative and Degenerative Arthritis*

| | Proliferative | Degenerative |
|---|---|---|
| Etiology ........ | 1. Foci of infection<br>2. Disturbed metabolism<br>3. Environment<br>4. Hereditary constitutional defects<br>5. Vascular instability<br>6. Gastro-intestinal malfunction | 1. Senility<br>2. Vasomotor disturbance<br>3. Trauma<br>4. Infection |
| Onset ........... | Acute or subacute | Insidious, chronic |
| Age group....... | Younger; 20-40 | Older; 40-60 |
| Type of joint.... | Increased fluid with fusiform swelling | Usually dry with general diffuse enlargement; crepitus often occurs |
| Sex ............. | Three times as common in females | Slightly more common in males |
| Joints affected.... | Smaller joints of hands and feet first<br>Often symmetrical involvement of joints: wrists, knees, ankles<br>Spine and jaw joint often involved | More commonly monarticular<br>Hip joint<br>Shoulder<br>Not symmetrical |
| Muscular wasting. | Marked | Not prominent |
| Pain ........... | Usually marked | Usually not marked, although very variable |
| Limitation of motion and deformity | Early and marked<br>Ankylosis early, fibrous or osseous | Usually comes on after years<br>Not real ankylosis; limitation often due to exostosis |
| Vasomotor phenomena | Often precedes actual development of arthritis<br>Raynaud's: cold hands, increased sweating | Arteriosclerosis common |
| Constitutional symptoms | May be marked | Usually not marked |

certain of the arthritides as infectious, one is apt to infer that the others are noninfectious. Such a conclusion again is unwarranted, since other data may be produced indicating that all types of arthritis are infectious, beginning with rheumatic fever, leading through so-called atrophic arthritis and including also ostearthritis. McCrae[11] expresses such an opinion, and other workers in the field are inclined toward this view. Thus it appears that at present any attempt to classify the arthritides on an etiologic basis alone is premature and apt to confuse the subject rather than to do the opposite. It is, however, important to present what etiologic data one may possess in any individual case and to use these data along with other information more fully to describe any given type of arthritis. With the recent interest in chronic arthritis, it is important that the cases be fully and accurately described. The use of the term chronic infectious arthritis (nonspecific)[5] does not offer such a description. In a recent paper on the value of prostatic treatment in arthritis,[12] simply the general term "chronic arthritis" is used without further differentiation, making it impossible to extract from this comprehensive study any information as to the type of arthritis in which prostatic massage might be of benefit.

The lack of logic in an old classification[13] of arthritis into (1) infectious, (2) atrophic and (3) hypertrophic has been pointed out by a number of writers, among them Osgood. Yet the classification was recently used anew.[14] The use of the term infectious arthritis in this classification is unfortunate, as it easily implies that the other two groups are noninfectious. This classification is commonly used by roentgenologists and has led to a great deal of confusion. It is common to receive an x-ray report of infectious arthritis in one patient and of atrophic arthritis in another and find the two patients identical from every clinical point of view. Roentgenologists wish to name such cases infectious arthritis when there has been a rapid destruction of the joint structure with marked erosion of the cartilage, abundant effusion into the joint and but little bone atrophy. In their experience, arthritis caused by a specific infection often presents such a picture. However, if one studies a series of cases of atrophic arthritis over a period of years, one will observe in the roentgenograms any one of the changes designated as specific for "infectious arthritis." Some joints are destroyed rather rapidly while others reach the same end-result only after a period of years. Surely the roentgenologist is not able to differentiate an infectious from a noninfectious joint process from the study of his film alone when many years of bacteriologic and clinical studies have failed to give such much needed information. It would result in less confusion if the roentgenologist simply described the pathologic process as revealed in the film rather than attempting to label the specific type of arthritis.

A few remarks might be appropriate in regard to some other phases of roentgen diagnosis in chronic arthritis. Not uncommonly a diagnosis of gonorrheal arthritis is made merely on a roentgen report. It is doubtful whether there are any specific roentgen indications in gonorrheal arthritis. It is certain that any of the roentgen changes found in a known case of gonorrheal arthritis may be present in ordinary atrophic arthritis. Clinicians too often are led to make the diagnosis gonorrheal arthritis when before the roentgen examination gonorrhea was not considered. Having received a roentgen diagnosis of gonorrheal arthritis, one searches and often obtains a history of gonorrheal urethritis years previously, with some persisting evidence of urethral disease; from then on the case becomes one of chronic gonorrheal arthritis. It is doubtful whether chronic gonorrhea produces chronic arthritis. The arthritis associated with gonorrhea usually comes on as an acute process a few days or weeks after the onset of a urethritis. A roentgen diagnosis of chronic gonorrheal arthritis is insufficient evidence on which to make the clinical diagnosis of this type of specific arthritis. It is necessary in most instances to obtain a history of the inception of the articular process soon after the onset of the gonorrheal infection.

The situation in regard to the roentgen diagnosis of gout is similar to that of gonorrheal arthritis. The roentgenologist makes the diagnosis of gout on punched out areas seen in the bones at the margins of the joint surfaces. Such so-called characteristic punched out areas are commonly seen in atrophic arthritis, as was pointed out many years ago by Strangeways,[4] by Henry Christian and by McClure and McCarty.[15] Only when the punched out areas are localized to the great toe joint can one be fairly certain that gout is present.

Umber's classification[6] into (1) infectious, (2) endocrine and (3) ostearthritis may be questioned from the same point of view as other etiologic classifications. As pointed out by Assman,[6] our knowledge of endocrine disease and arthritis is so fragmentary that a classification based on this limited information is apt to lead to further misrepresentation. Beneke's classification[6] into (1) physical and (2) chemical would seem to add little or nothing to the clarity and understanding of the subject. Assman's[6] groups (1) inflammatory, (2) noninflammatory correspond closely to Nichols and Richardson's (1) proliferative, (2) degenerative, different terms being used to designate the same pathologic processes.

In regard to the classification proposed by the American committee, investigators are finding that they are unable to describe adequately certain joints in a way sufficiently clear to exclude mistakes. The classification gives only one phase of the disease. It is too fixed and does not permit the free incorporation of new information.

The present paper is entirely eclectic. I wish to enlarge on the classification proposed by the committee, making it less archaic, more descriptive and at the same time, be it freely admitted, more cumbersome. The classification of chronic arthritis here proposed is not based on any one particular phase but tries to consider the phases of the subject that seem important: the clinical, etiologic, pathologic, anatomic and roentgenologic aspects. Such a compound classification has recently been suggested by Fisher.[16] It is hoped that the use of this type of classification will give a complete unmistakable picture of any type of arthritis. It allows for addition or subtraction as experience warrants, without destroying the general structure. It is true that the resulting terminology is cumbersome, but until one is able to formulate a classification based on known etiology, lengthy descriptive terms seem necessary.

[16] Fisher, A. G. T.: Chronic (Nontuberculous) Arthritis, New York, Macmillan Company, 1929.

It is evident from table 2 that three different aspects are presented. Of these, the pathologic is the most general and is further specified and determined by the additional use of the anatomic and the roentgenologic terminology. Another independent aspect is the clinical one, simple in concept but fundamental in importance. The third aspect is the etiologic, independent of the other two. Particularly in reporting the results of different types of treatment it seems paramount clearly to indicate what kind of process has been treated and which symptoms have been relieved. A treatment leading to objective improvement must be considered differently from one giving chiefly subjective relief. An analytic presentation is needed as much in the evaluation of the therapeutic results as in the description of the patients subjected to the treatment.

Great interest at present centers around the possibility of further development of the etiologic diagnosis. A brief discussion seems indicated. In spite of the amount of evidence in favor of the streptococcus as a causative agent in chronic arthritis, there is no unanimity of opinion in this matter. The streptococcic theory has gained ground in English speaking countries, while German investigators are less convinced that the streptococcus is the specific organism; they still hold out the possibility of an undiscovered filtrable virus.

Table 2.—*Facts to Be Considered in Classification of Arthritis*

| Clinical | Etiologic | Pathologic | Anatomic | Roentgenologic |
|---|---|---|---|---|
| Acute<br>Subacute<br>Chronic<br>Recurrent<br>———<br>Monarthritis<br>Polyarthritis | Specific infections<br>Gonorrhea<br>Staphylococcus<br>Streptococcus<br>Traumatic<br>Metabolic (gout)<br>Arthropathic<br>Charcot<br>Syringomyelia | Proliferative<br>Degenerative | Periarticular (synovial)<br>Chondro-osseous<br>Mixed | Atrophic<br>Hypertrophic |

Examples:
Subacute periarticular atrophic arthritis
Chronic proliferative (chondro-osseous atrophic) arthritis
Acute staphylococcic proliferative (periarticular) arthritis
Subacute gonorrheal proliferative (mixed) arthritis
Chronic streptococcal proliferative (periarticular atrophic) arthritis
Chronic degenerative (chondro-osseous hypertrophic) (mon)arthritis

The enthusiasm over the rôle of the streptococcus in acute rheumatic fever has led some investigators to conclude that all types of arthritis are manifestations of the same infection. Streptococci have been found in the blood and joints not only in rheumatic fever and rheumatoid arthritis but also in ostearthritis. These workers are inclined to believe that the variations in the clinical picture are due simply to age differences in reaction to one and the same infecting organism. That is, when a child is afflicted with rheumatic disease he develops rheumatic fever; a young adult gets rheumatoid arthritis, while an older adult gets ostearthritis. Thus there has been some tendency to disregard all previous clinical classifications and to throw all types of rheumatic and joint infection into one undifferentiated group. While there is some evidence in favor of this point of view, it would lead to confusion if the well recognized clinical types of arthritis were disregarded. It is difficult to conceive that rheumatic fever and rheumatoid arthritis are manifestations of the same disease. There are too many and too marked differences between them; rheumatic fever is a disease of childhood having its peak of incidence at about 9 years of age. Rheumatoid arthritis occurs most commonly between 20 and 30 years of age. Rheumatic fever is ordinarily more acute but practically never leads to permanent joint changes, as is usually the case in rheumatoid arthritis. Rheumatic fever causes permanent damage of the heart in 60 per cent of the cases, while valvular heart disease is a rare complication in the rheumatoid type. If these two diseases were different manifestations of the same infection, one would expect to find at least a small number of patients who showed definite progress from the state of rheumatic fever to that of rheumatoid arthritis. I have had the opportunity of observing several hundred cases of juvenile rheumatism during the past eleven years. The children have been followed through the high school period into young adulthood and in not a single case has the transition from rheumatic fever to rheumatoid arthritis been observed. Occasionally a child shows some persistent swelling and stiffness of the joints after the acute stage of the rheumatic fever has passed, but in no instance has this condition led to rheumatoid arthritis and in no case have there been roentgen changes characteristic of the rheumatoid type. If these two types of rheumatism are due to the same infecting agent, it is strange that cases of mitral stenosis accompanying rheumatoid arthritis are not observed. On the other hand, when rheumatoid arthritis occurs in childhood, as it occasionally does, it presents the same picture as in the adult. Still's disease appears to be nothing but rheumatoid arthritis in childhood.

The study of rheumatism in Holland[17] has shown that, while rheumatoid arthritis is common, rheumatic fever is rare. A more nearly identical occurrence of these rheumatic conditions might be expected if the causative agents were the same. It seems evident that there are fundamental differences between rheumatic fever and rheumatoid arthritis.

As already indicated, there are also fundamental differences between rheumatoid arthritis and ostearthritis. The rheumatoid type appears to be an infectious disease, while ostearthritis possesses none of the characteristics of an infectious process. While there is some overlapping between the groups, ordinarily they can be differentiated clinically.

Until the etiology of the various types of rheumatic disease is determined, it is important to maintain a clear clinical classification. Starting with the fundamental differentiation given by Nichols and Richardson and adding other significant phases, it is possible to describe clearly any particular case. It would seem a distinct advantage if attempts at classification based exclusively on presumptive etiology were discontinued.

## SUMMARY

The classification of chronic arthritis recently proposed by the American Committee for the Control of Rheumatism has not been universally accepted.

A brief review of the recent literature on chronic arthritis shows a number of classifications which are controversial.

The composite classification of arthritis introduced in the present article permits the use of descriptive terms the meanings of which are unmistakable.

# PULMONARY SYPHILIS

## A REPORT OF THREE CASES OF ACQUIRED LUNG SYPHILIS IN ADULTS, WITH PARTICULAR REFERENCE TO ROENTGEN ASPECTS

ADOLPH HARTUNG, M.D.
AND
JOHN FREEDMAN, M.D.
CHICAGO

A diagnosis of pulmonary syphilis is generally regarded with a good deal of skepticism. A brief survey of the literature reveals marked variations of opinion as to incidence, character of the lesion and anatomic criteria essential for the establishment of an authentic diagnosis. Carrera,[1] in a very careful postmortem study of the lungs of 152 known syphilitic patients, found 12 cases of undoubted syphilis of the lungs from the anatomic standpoint. In 29,680 routine postmortem examinations collected by Erickson, syphilis of the lung was found in but 19 instances (0.06 per cent) in 240 autopsies on known patients with syphilis, the disease occurred in 23 cases (9.6 per cent).

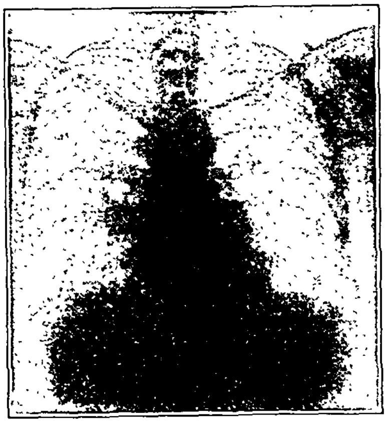

Fig. 1 (case 1).—Appearance March 12, 1930, just before antisyphilitic treatment was begun. A slight extension had occurred since the previous roentgen examination.

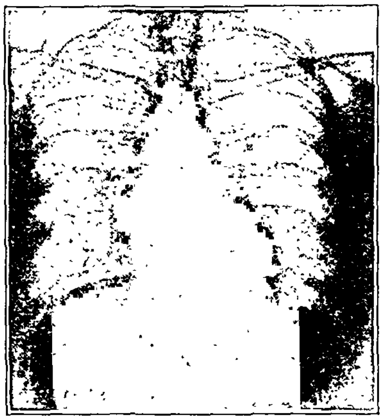

Fig. 2 (case 1).—Appearance about six and one-half months after antisyphilitic therapy: evidence of retrogression; Wassermann reaction still strongly positive.

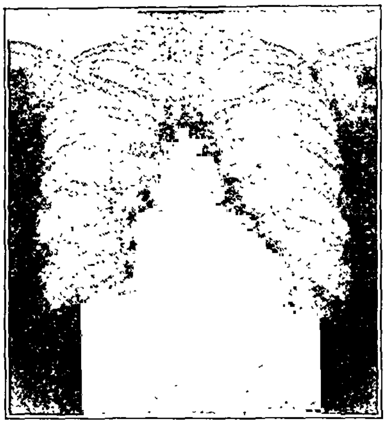

Fig. 3 (case 1).—One year after syphilitic treatment: almost complete regression; Wassermann reaction negative.

In the present article we record three cases and discuss the salient features of the condition.

Case 1.—G. M., a Negress, aged 25, married several times, never pregnant, was well until May, 1928, when she was acutely ill with cough, chills, fever, mucous expectoration, and pain in the right chest. A diagnosis of pneumonia was made from which she did not recover entirely. She was admitted to the hospital for observation, Sept. 30, 1929. She did not look or feel acutely ill. There was a persistent morning cough with thick mucous expectoration, at times blood streaked. She had lost 65 pounds (29.5 Kg.) and had had gnawing pains across the back of the chest since the illness in May. A tentative diagnosis of unresolved pneumonia was made. Physical examination disclosed some râles in the bases of both lungs. Eight sputum examinations both before and after antiformin treatment were invariably negative for tubercle bacilli. Repeated Kahn and Wassermann tests were 4 plus. Up to time of antisyphilitic treatment there was little change in her condition. Following this she improved rapidly and when last seen she was symptom free.

The first roentgen examination, Sept. 25, 1929, showed multiple small nodular infiltrations scattered through the parenchyma of both lungs, especially the right one. The right hilar shadow was markedly increased and there was some fibrosis of the interlobar pleura between the upper and the middle lobe. On the left side most of the lesions were located in the base. The conditions found were interpreted as consistent with a pulmonary tuberculosis of a disseminated or miliary type. The possibility of a bronchiectasis or pneumonoconiosis was given consideration. A clinical diagnosis of pulmonary tuberculosis was made at the time of her first discharge from the hospital. However, the striking disproportion between the roentgen changes and the clinical observations, especially in view of the repeated negative sputum examinations, subsequently caused doubt as to the correctness of such a diagnosis. A second roentgen examination, March 12, 1930 (fig. 1), showed a slight increase of the infiltrations, particularly on the left side. Clinically, there had been little change in the patient's condition since first seen. Because of positive serologic reactions for syphilis, antisyphilitic therapy was instituted, April 2. A third roentgen examination, Oct. 15, 1930 (fig. 2) showed very definite evidence of regression, especially in the upper lobes. Serologic tests at this time were still positive. A roentgen examination, April 1, 1931 (fig. 3), showed almost complete disappearance of the original nodular infiltrations except for a few at the bases of both lungs. Increase of the right hilar shadow and of the linear markings in the lower lobes was still present, undoubtedly the result of an interstitial fibrosis. Serologic examinations, April 2, 1931, were negative. The patient at this time was symptom free.

Case 2.—O. A., a white man, aged 35, single, a Scandinavian, who registered at the clinic Aug. 19, 1930, had had epigastric pain shortly after meals, of two months' duration. He had had a persistent cough for years. He had lost 25 pounds (11 Kg.) in the past four or five months. Examination revealed palpable epitrochlear glands and some physical signs in the left base. Repeated sputum examinations were negative for tubercle bacilli. Repeated serologic examinations at intervals were 4 plus. Antisyphilitic treatment was begun September 27, following which there was marked general clinical improvement and gain in weight. When last seen the patient was symptom free but his Wassermann reaction was still 4 plus.

The roentgen examination of the gastro-intestinal tract, for which the patient was originally referred, was essentially negative. During the routine preliminary fluoroscopic examination of the chest in connection with it, a tumor-like mass was noted in the base of the left lung. Films made Nov. 10, 1930, showed this as a circumscribed shadow of uniformly increased density, about the size and shape of a hen's egg in the sixth intercostal space on the left side near the lateral chest wall. Some increase of the hilar shadows and linear markings was present on the left side and a few small localized infiltrations with calcification were noted in the right lower lobe. The latter changes were interpreted as the remains of an old and probably healed hilar tuberculosis and were thought to have no relation to the present condition. The solitary soft mass which apparently was in the left lower lobe was thought to be a tumor, possibly of metastatic origin. In view of the absence of a demonstrable primary

[1] Carrera, J. L.: A Pathologic Study of the Lungs in One Hundred and Fifty-Two Autopsy Cases of Syphilis, Am. J. Syph. 4: 1-33 (Jan.) 1920.

malignant tumor of which this might be a metastasis and the improbability of its being malignant from its clinical manifestations, the possibility of its being a gumma was given consideration, especially in view of the positive results shown on serologic examination. Antisyphilitic treatment was instituted, Sept. 27, 1930. A roentgen examination, April 7, 1931, showed definite evidence of regression of the tumor mass. It was less sharply localized and decidedly smaller. The other lung changes showed no appreciable difference from the previous examination. A roentgen examination, Jan. 19, 1932, showed practically complete disappearance of the lesion. Serologic tests at this time were still positive, indicating a Wassermann-fast condition.

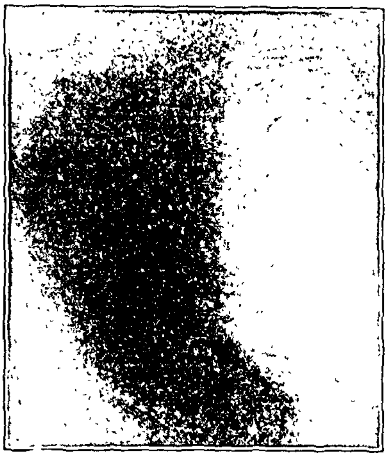

Fig. 4 (case 3).—Marked pleural thickening; atelectasis of right lung; Wassermann reaction strongly positive.

A review of these two cases, which showed clinical and serologic evidences of syphilis with pulmonary lesions compatible with known pathologic processes of that disease and the disappearance of these lesions as observed roentgenologically with antisyphilitic treatment, together with clinical improvement, seems to justify a diagnosis of pulmonary syphilis in the form of miliary gummas in case 1 and a solitary giant gumma in case 2.

Case 3.—M. C. R., a white man, aged 55, married, Irish, a conductor, registered at the clinic, Oct. 4, 1929, having had irregular periodic attacks of chills and fever (104 F.) lasting about an hour at intervals usually from four to seven days apart for about four years. He also had a persistent cough, particularly in the morning, with a blood-streaked expectoration of from 6 to 8 ounces. He showed dyspnea on exertion. He had lost about 15 pounds (6.8 Kg.) in the last two years. He had had recurrent attacks of bronchitis for ten or fifteen years. He had been married twenty-two years. There were no children. His wife had had two miscarriages. He had had gonorrhea thirty years before. Examination revealed a slight retraction of the right chest wall below the clavicle, increased tactile fremitus, dulness, crackling râles and impaired sounds on auscultation over the entire right lung. The left lung showed hyperresonance. The heart was displaced toward the right. About fifty or more sputum examinations with and without antiformin treatment, made at intervals for about three years, were negative for tubercle bacilli and elastic fibers. A thoracentesis of the right chest, Nov. 11, 1929, was dry. Serologic tests, Nov. 6, 1929, were 4 plus. Following antisyphilitic treatment the reaction was less marked, but shortly before death it again showed 4 plus. A right phrenic exeresis was done June 5, 1930, with slight, if any, improvement. The patient died with signs of cardiac decompensation. The clinical diagnosis was atelectasis of the right lung with chronic pleuritis and bronchiectasis, and emphysema of the left lung. Syphilis, but not syphilis of the lung, was considered a coincident condition.

Roentgen examination of the chest, Oct. 7, 1929 (fig. 4) showed a diffuse increased density of the right chest extending to about the level of the sternal end of the second rib and irregular density above this. The heart and other mediastinal structures were displaced toward the right. Increased radiolucency of the left lung indicated a probable compensatory emphysema. Some increase of the linear markings was noted, suggesting an interstitial fibrosis. The conditions on the right side were interpreted as consistent with an atelectasis possibly associated with a bronchogenic carcinoma and bronchostenosis of some of the larger bronchi. The possibility of a marked pleural fibrosis in connection with a fibroid phthisis or following an acute or unresolved pulmonary lesion was considered. The probability of an associated bronchiectasis was suggested. November 11, another roentgen examination was made following the injection of iodized oil (fig. 5). Because of the extreme density of the right chest the oil accumulations in the lung showed up poorly, but bronchial dilatation was clearly demonstrable in the larger bronchi. In view of the prolonged course and absence of demonstrable progressive changes during a lengthy period of observation, the probability of bronchogenic carcinoma was ruled out. Another roentgen examination, May 28, 1930 (fig. 6), about six months after antisyphilitic treatment was instituted, showed practically no change roentgenographically. Some iodized oil residues were still present. A final roentgen examination, Jan. 16, 1932 (fig. 7), shortly before death, showed almost identically the same condition noted on the first examination.

The lung changes found at autopsy by Dr. George Milles were as follows: The right pleural cavity was completely obliterated by dense fibrous adhesions. The pleura averaged 5 mm. in thickness and was pale gray. The underlying lung was firm and noncrepitant, and on section the parenchyma was dense and varied from dark gray to black. The bronchi even to the minor subdivisions were widely dilated. The interlobar septum was pearly gray, dense and sclerotic, averaging 8 mm. in thickness. Microscopically the alveoli were almost entirely obliterated or completely compressed, being replaced in a large portion of the section by dense hyalinized fibrous tissue. Scattered through this were seen focal collections of round cells, about the fine bronchioles and blood vessels. These round cell collections were made up of lymphoid cells, many plasma cells and an occasional macrophage. The blood vessels present were the seat of marked intimal proliferation with hyaline changes. Many newly formed capillaries were seen scattered through the tissue. A single large artery present in the sections displayed the same intimal proliferation. The bronchioles were dilated and surrounded by a zone of granulation tissue, in which plasma cells were especially numerous.

The left lung showed essentially the changes of an emphysema and a rather marked proliferation of interstitial fibrous tissue. Other organs examined showed nothing relevant to the subject under discussion.

Dr. Milles expressed the opinion that the pulmonary and pleural changes were not characteristic of pulmonary syphilis but some of them might have been of syphilitic origin and others might be in the nature of sequelae. Dr. R. H. Jaffe, to whom the gross specimen and sections of the right lung were also shown, concurred in this opinion.

Reconstructing this case in view of the clinical course, positive serologic examination and autopsy observations, the inference that it was a case of lung syphilis in a very late stage with accompanying sequelae seems justified.

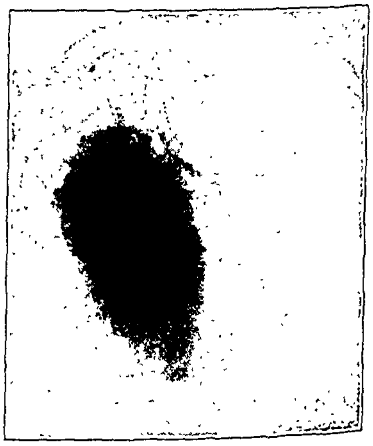

Fig. 5 (case 3).—Bronchogram showing patency of primary bronchi, atelectasis of right lung, and bronchiectasis.

## COMMENT

Lung syphilis, when it occurs, is never primary and is only an incidental location of attack in the widespread ravage of the disease throughout the body. The early cases under adequate antisyphilitic treatment clear up, apparently. The unrecognized neglected cases are slowly progressive. The syphilitic lesion or lesions are slowly absorbed, leaving connective tissue and massive scars. The densely thickened pleura and interlobar septums contract, producing considerable compression of lung substance with secondary atelectasis and bronchiectasis. The pulmonary circulation suffers obstruction; the work of the right ventricle is overloaded; cardiac hypertrophy and decompensation follow; as a result of the chronic passive congestion there is an increase of the lung fibrosis; general circulatory failure ultimately ushers in death.

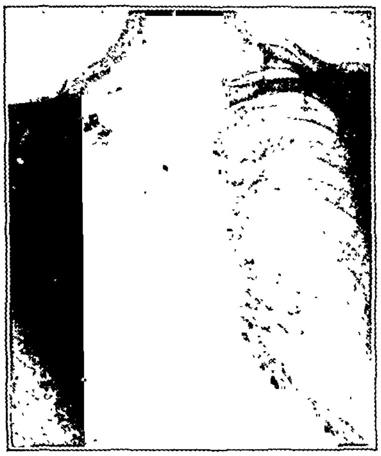

Fig. 6 (case 3).—Condition after five months of antisyphilitic treatment: no progress nor retrogression; some residual iodized oil present.

Clinically, the diagnosis is made more frequently than it is confirmed anatomically. The reason is obvious. In a great majority of the reported cases the diagnosis has been based on clinical evidence and many of the cases have resulted in an apparent cure. Therefore, the ultimate proof is, as a rule, wanting. The diagnosis is a matter of exclusion, and an attempt should be made to satisfy the following criteria:

1. History of syphilis—chancre, mucocutaneous lesions, cardiovascular syphilis, syphilis of the larynx, stigmas of syphilis anywhere—miscarriages and stillbirths.

2. Signs and symptoms of a chronic stubborn progressive pulmonary lesion. In syphilis of the lungs there is a disproportion of symptoms to signs. The signs are marked and the symptoms mild.

3. Repeated examinations of the sputum to rule out tuberculosis, mycotic infections and other spirochetal infections such as Vincent's infection of the lungs. Since the discovery of the tubercle bacillus, case reports of lung syphilis have become increasingly rarer.

4. Demonstration of Spirochaeta pallida—dark field or specific tissue stain. It is only rarely that spirochetes have been demonstrated in unquestionable tertiary syphilitic lesions in general. It is not to be expected, therefore, that spirochetes will be found in gummas of the lungs.

5. Serologic examinations. When positive, they indicate the presence of syphilis but do not mean that a pulmonary lesion is necessarily syphilitic.

6. Roentgen examinations. When these show evidence of chronic pulmonary disease involving the root, middle lobe or base of the lung in a patient with unquestionable evidence of syphilis and in whom tuberculosis has been ruled out by every available means, the possibility of syphilis of the lung should be given consideration either alone, as a complication, or as a coexistent condition.

7. Therapeutic test. Improvement under antisyphilitic treatment is contributory evidence in its favor but is by no means absolute. This is the deciding factor in the clinical diagnosis. There is general clinical improvement—disappearance of symptoms—as well as a local clearing up of the lesion. Spirochetal infection of the lungs other than syphilis yield to treatment with ease; syphilis, with difficulty. It is, however, as a rule very difficult to secure permanently negative serologic reactions in any form of late syphilis, and this has been true of some pulmonary cases.

8. Anatomic confirmation wherever possible—syphilitic changes about the nature of which there can be no doubt. This is the court of last appeal.

The finding of Spirochaeta pallida in the sputum of acquired syphilis of the lung is extremely difficult, so that confirmation depends entirely on the specific anatomic changes produced by the organism. It is very probable that many more lungs are syphilitic than is generally believed, but the syphilitic changes are not found and it is only on these that a positive diagnosis can be made; hence the relative infrequency of the condition.

The physical signs and symptoms are variable and not distinctive. They give no inkling as to the nature of the lesion present. They are usually those of the secondary conditions—thickened pleura, fibrosis, bronchiectasis, or any other chronic progressive lung condition—and cannot be differentiated from any of these clinically.

Syphilis attacks chiefly the lower part of the lung, rarely the apexes, the process being more marked around the hilus and progressing along the bronchi toward the periphery. It tends to develop unilaterally and may completely destroy the function of one lung with little or no involvement of the other. Syphilis also involves the pleura extensively and causes a connective tissue reactio [illegible] ating or stellate scars but rarely, if [illegible]. In the early untreated cases one may see single or multiple gummas varying in size from a pea to a hen's egg, surrounded by syphilitic infiltration—lymphocytes and plasma cells—perivascular with obliterating endarteritis. Fibrosis, scarring, is the late phase or sequel of the syphilitic process. Regarded as of probable syphilitic origin is the puckered, indurated, dense, radiating scar formation sometimes found on the lung surface or about the larger bronchi within the lung substance and in the interlobar and interlobular septums producing the so-called pulmo lobatum of Virchow. This tissue consists of dense massive connective tissue, which by its contraction has more or less distorted the lung. One can only surmise that in some cases this may represent the healed result of a preexisting gumma. However, as the lung is susceptible to many injurious agents—both bacterial and foreign bodies—such puckered, radiating scars cannot with any certainty be regarded as of syphilitic origin. Virchow advised great caution in making such a diagnosis. Unless syphilitic infiltration is shown, a positive anatomic diagnosis of syphilis cannot be made.

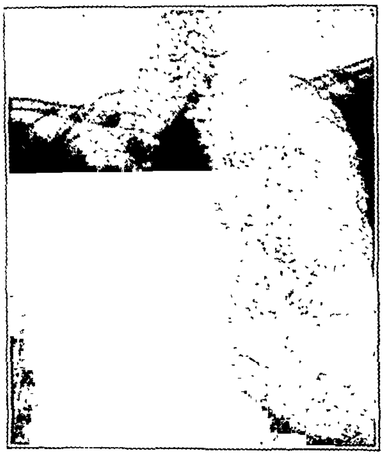

Fig. 7 (case 3).—Appearance shortly before death, practically the same as on the first examination; Wassermann reaction strongly positive.

No dogmatic statements in regard to the roentgenologic appearance of pulmonary syphilis can as yet be accepted. There are no pathognomonic or characteristic signs. Gummas with syphilitic peribronchial infiltration show increased linear markings in the early stages with small "knobby" enlargements. There may be diffuse miliary gummas simulating tuberculosis. Giant gummas vary in size, shape and number, and the roentgen images they produce may simulate lung tumors or localized pneumonitis. In the late stage the syphilitic fibrosis shows extensive increase in bronchial shadows without gummatous enlargements. The fibrosis, which is so common, is the same as might result from any nonspecific inflammation. In the very late neglected cases there may be a bronchostenosis with collapse of the lung resulting from syphilitic ulceration and scarring, and the resulting atelectasis is invariably associated with dilatation of the bronchi, producing the picture of bronchiectasis. A diffused increased density involving an entire half chest may be present, produced by a combination of factors such as markedly thickened pleura and interlobar septums with atelectasis from compression, scar contraction of lung substances with marked retraction of the heart, trachea and other mediastinal structures to the affected side, elevation of the diaphragm on the affected side, and compensatory emphysema of the opposite lung. Syphilitic lesions rarely undergo cavity formation; they are slowly absorbed, leaving massive scars with absence of calcification as compared to tuberculous scars.

The roentgen examination is of the utmost importance in the differential diagnosis, especially in eliminating certain other conditions. Regressive changes of lesions in the lung consistent with syphilis, demonstrable roentgenologically and occurring simultaneously with antisyphilitic treatment, are of the greatest importance in establishing a clinical diagnosis of pulmonary syphilis. In cases measuring up to the other criteria, such roentgen observations would seem to clinch a positive diagnosis as far as this can be done clinically.

### CONCLUSIONS

1. Clinical diagnoses of lung syphilis with certainty are extremely difficult and fraught with danger in compiling statistics.
2. Working clinical diagnoses are justifiable for treatment and observation.
3. Anatomic confirmation is essential for acceptance of authentic cases.
4. Clinically, the diagnosis is made by exclusion and therapeutic test, and certain requirements must be fulfilled.
5. Roentgen observations as shown by successive examinations in connection with antisyphilitic treatment are of prime importance in establishing a clinical diagnosis.

**The Tonsils.**—The contention that normal tonsils are an aid in resisting disease is not strongly defended by contrasting the histories of disease of those with normal and those with pathologic tonsils. The argument that the removal of tonsils closes a portal of entry for infectious and respiratory diseases is not sustained by a comparative study of the histories of those who have had their tonsils removed and of those whose tonsils are present. The effect of the tonsils as a focus of infection does not find much support when histories and physical measurements of those with pathologic tonsils are contrasted with either those with normal or those with absent tonsils.—Cunningham, R. L.: Normal, Absent and Pathologic Tonsils in Young Women, *Arch. Int. Med.* **49**:453 (March) 1932.

# DIVERTICULUM OF THE EPIGLOTTIC VALLECULAE

## REPORT OF TWO CASES

CARL GOLDMARK, M.D.
Visiting Physician of the Lebanon Hospital
AND
THOMAS SCHOLZ, M.D.
NEW YORK

The epiglottic valleculae are two depressions situated between the base of the tongue and the epiglottis, one on each side of the median glosso-epiglottic ligament.

The space underneath the valleculae, between the lower part of the epiglottis and the membrana hyothyroidea, is occupied by a mass of loose fatty and connective tissue and the bursa mucosa subhyoidea.

One would imagine that during the first act of deglutition, when the food is conveyed from the oral cavity into the opening of the esophagus, particles of food would be held back by the epiglottis and become lodged in the vallecular depressions. Roentgenologic studies of the act of swallowing, however, have shown that under normal conditions this does not occur. It has been definitely demonstrated that the mechanism of deglutition—consisting of lifting, constricting, propelling movements and a simultaneous bending backward of the epiglottis—conveys each bolus of food in its entirety into the relaxing opening of the esophagus within a fraction of a second.

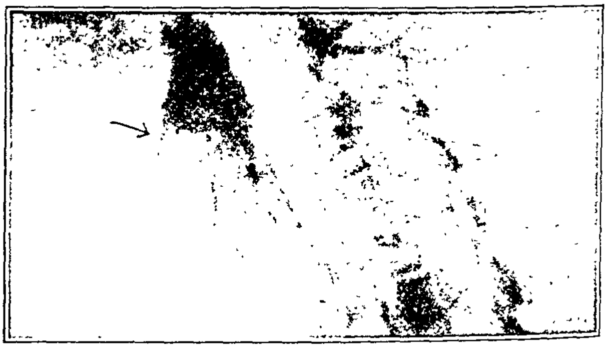

Fig. 1.—Complete filling and marked enlargement of the pre-epiglottic space, thirty seconds after swallowing of the contrast mixture.

However, as soon as some interference with the swallowing apparatus arises, as in instances of paralysis, the physiologic action becomes altered. Thus in vagus or recurrens paralysis, after the main portion of the swallowed bolus has passed into the esophagus, one sees appreciable remnants of food still remaining in the valleculae or occasionally also farther down in the sinus pyriformes.

Roentgenologically, such cases present a characteristic appearance. Retention of the contrast mixture in the valleculae shows a small, well defined shadow slightly below and posterior to the body of the thyroid bone, while on the other hand stagnation within the pyriform sinuses is recognized by striplike vertical shadows, one on each side of the thyroid cartilage.

Several such cases have been recorded in the literature. Thus, Assmann[1] describes a case of mediastinal tumor with secondary bilateral recurrens paralysis in which marked stagnation of food in the valleculae was found. A similar condition was observed by him in a case of tabes with secondary paralysis of the vagus. In a third case, in which botulism had caused an injury to the vagus nerve, roentgen examination revealed retention of the contrast food in the valleculae and the sinus pyriformes associated with widening of the esophagus. Reiche[2] reports an instance of pre-epiglottic food retention in diphtheritic paralysis. Weingaertner[3] mentions a case of carcinoma of the upper part of the esophagus with secondary paralysis of the recurrens nerve. In this case within the epiglottic region was a marked stagnation of contrast fluid, which overflowed into the trachea and bronchi. A very similar case was described by Desseker.[4]

---

[1] Assmann, H.: Die klinische Roentgendiagnostik, Leipzig, F. C. W. Vogel, 1929, p. 210.

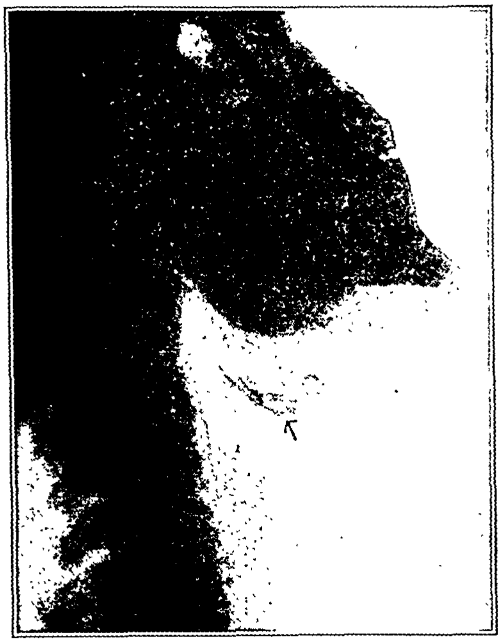

Fig. 2.—The same patient as in figure 1 two hours later. The pre-epiglottic space still shows a small amount of barium mixture.

Another explanation for the pre-epiglottic retention of food was brought forward by Holzknecht and Olbert.[5] In certain evidently neuropathic persons in whom fluoroscopy revealed marked stagnation of food along the anterior surface of the epiglottis and in the valleculae, they found an unusual relaxation of the entire esophagus. The retention was explained on the basis of atony. This theory, which apparently had remained unnoticed, was recently strengthened by the studies made by Paluguay.[6] He showed that esophageal atony may cause more or less marked stagnation in any part of the path of deglutition.

To the foregoing causes of food retention within the valleculae, we add that of pre-epiglottic diverticulum which apparently has not yet been described. The characteristic clinical and roentgenologic observations in two cases seem to justify their publication in view of the rareness of the condition.

## REPORT OF CASES

Case 1.—M. K., a physician, aged 60, had been complaining for the past five years, but especially during the past five months, of irritation in the throat, which was most evident some time after meals. He had the feeling as if particles of food "got stuck somewhere in the upper part of his throat." This condition was occasionally associated with pain on swallowing, swelling in the submaxillary regions, and local tenderness. Laryngoscopy failed to give any positive results.

Fluoroscopy of the esophagus with the aid of thin and moderately thick barium mixtures showed complete and permanent filling of the pre-epiglottic space. The latter was greatly widened and deepened, its floor reaching far below the body of the hyoid bone (fig. 1). Prolonged fluoroscopic observation revealed intermittent contractions of the epiglottic region with resultant emptying of some of the fluid from the pre-epiglottic sac. After two hours only a small amount of the contrast medium could be seen (fig. 2). The passage through the esophagus was normal. There was no evidence of spasticity or atony. Lungs, heart, aorta and mediastinum also presented a normal appearance.

The patient was reexamined repeatedly during the following two years. The roentgen appearance remained the same. All therapeutic suggestions proved unsuccessful. The patient, however, had gradually learned to lessen the discomfort by the repeated drinking of small amounts of water after each meal.

Case 2.—Mrs. W. S., aged 62, complained quite suddenly during the night of a fulness in the left side of her throat associated with a stitching pain and difficulty in swallowing. The most distressing part to the patient was the feeling of a lump in the throat which she could not dislodge. When she was seen the following morning the attack had subsided, but a slight local tenderness on the left side of the neck persisted. There was no glandular enlargement. Examination of the throat and larynx was negative with the exception of an elongated uvula touching the epiglottis.

The further history, which was obtained with difficulty on account of the insignificance of the symptoms, revealed that for the past three or four months there had been peculiar sensations in the throat, especially after meals. Occasionally some foul material would be expectorated. Vomiting occurred at times during the past four years without apparent cause or effort. (It is interesting to note that this effortless vomiting without apparent exciting cause is present in other members of the family. No opportunity has presented itself to study these other cases.) Other facts in her history are irrelevant as far as the matter in hand is concerned. With a tentative diagnosis of diverticulum of the upper part of the esophagus, the patient was referred for roentgen examination.

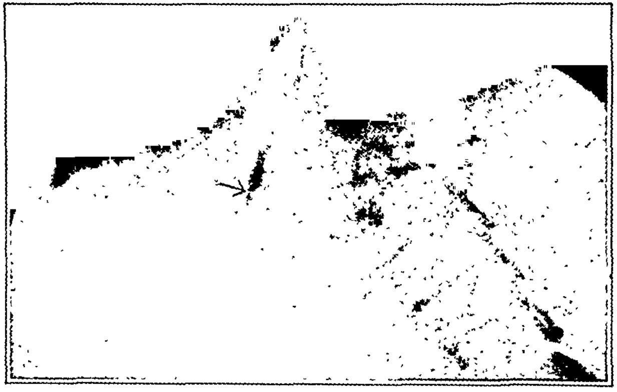

Fig. 3.—Small amount of barium mixture within the epiglottic valleculae one and a half hours after swallowing.

Fluoroscopic examination revealed an unusually large amount of barium within the pre-epiglottic space, which was definitely and markedly enlarged. Though it seemed that the pre-epiglottic region emptied readily enough, it was found on prolonged observation that appreciable remnants of the barium were still visible in the vallecular region, one and a half hours later, as seen in figure 3.

## THEORY OF THE FORMATION OF PRE-EPIGLOTTIC DIVERTICULA

There can be no doubt that the ability of the epiglottis to bend backward sufficiently during the act of deglutition forms one of the prerequisites for the prevention of food stagnation in the pre-epiglottic space. In other words, the epiglottis must always possess a certain amount of elasticity. The importance of this point may be considered stressed by the fact that calcification never takes place in the epiglottis.

[3] Weingaertner, M.: Wismut im Bronchialbaum bei Oesophaguskarzinom ohne Perforation nach den Luftwegen, Fortschr. a. d. Geb. d. Roentgenstrahlen **22:** 397-400, 1915.

[4] Desseker, C.: Beitrag zur pathologischen Physiologie des Schluckakts und zur Fuellung des Bronchialbaums mit Roentgenbrei, Mitt. a. d. Grenzgeb. d. Med. u. Chir. **37:** 41-50, 1924.

[5] Holzknecht, G., and Olbert, D.: Die Atonie der Speiseroehre, Ztschr. f. klin. Med. **71:** 91-115, 1910.

[6] Paluguay, J.: Zur Roentgendiagnose der Speiseroehrenatonie, Mitt. a. d. Grenzgeb. d. Med. u. Chir. **37:** 107-127, 1924.

It is fair to assume that with advancing age the elasticity of the epiglottis may occasionally decrease below the required minimum. In such an event, particles of food will accummulate in front of the epiglottis and may gradually lead to the formation of a pre-epiglottic diverticulum. This probably explains why our observations were made in elderly people.

### CONCLUSIONS

1. Pre-epiglottic diverticula are rare.
2. They seem to occur at an advanced age and may possibly be due to a loss of elasticity of the epiglottis.
3. Clinically they are characterized by a feeling of a lump in the throat after eating, with discomfort on swallowing, occasional regurgitation of foul material, swelling in the submaxillary region, and local tenderness, with no laryngologic changes.
4. Fluoroscopically the condition can be definitely diagnosed, especially if the observation is prolonged. The roentgen examination reveals enlargement of the pre-epiglottic space as outlined by the barium mixture, unusual spastic contractions of the epiglottic region, and persistence of the pre-epiglottic shadow for several hours.
5. We have no therapeutic suggestion to offer. The discomfort may be alleviated by frequent gargling with plain water after meals.

# INTRAVENOUS STREPTOCOCCIC VACCINE THERAPY IN CHRONIC ARTHRITIS

MACNIDER WETHERBY, M.D.
AND
B. J. CLAWSON, M.D.
MINNEAPOLIS

Subcutaneous injections of a streptococcic vaccine have been used extensively for many years in the treatment of arthritis. Both autogenous and stock vaccines have been tried. Some of the larger series of vaccinated patients have been those of Billings, Coleman and Hibbs,[1] Crowe[2] and Burbank.[3] Crowe and Burbank have reported favorable results. Billings, Coleman and Hibbs compared results of a large series of vaccinated patients with a series of unvaccinated patients. In a follow-up study they found no significant differences in the incidence of improvement in the treated and untreated groups.

There are few reports on intravenous streptococcic vaccination in the literature. Clawson and Fahr[4] reported the use of intravenous streptococcic injections in the treatment of rheumatic fever. Swift and his co-workers,[5] injected Streptococcus hemolyticus intravenously in the treatment of rheumatic fever. We[6] have used the intravenous method in administering a streptococcic vaccine in chronic arthritis. Gray and Gowen[7] vaccinated patients having chronic arthritis by combining subcutaneous and intravenous injections. It is of interest that they obtained more rapid and satisfactory results by the intravenous method.

Intravenous streptococcic vaccination of patients having chronic arthritis has for its basis the following observations derived from our previous experiments and observations by others:

1. Nonspecific chronic arthritis in most cases appears to be due to streptococcic infection. Streptococci have been recovered in a higher percentage by a greater number of workers from the blood,[8] joints,[9] lymph nodes[10] and subcutaneous nodules[11] in cases of chronic arthritis than any other organism.

2. Subcutaneous streptococcic vaccination does not desensitize the hypersensitive chronic arthritic patient but tends to increase the hypersensitiveness. The subcutaneous method of giving a streptococcic vaccine increases protective immunity only slightly.[12]

3. Intravenous streptococcic vaccination desensitizes the hypersensitive patient and also brings about a high degree of protective immunity.[13]

4. The desensitizing and protective phenomena do not seem to be strictly type specific but are species specific. They are not in the category of a reaction to nonspecific protein.[13]

5. The height of the streptococcic agglutinating titer furnishes a reliable indicator of the progress in the development of protective immunity during the course of treatment.[14]

### MATERIAL

The patients in our series were from the outpatient department of the University of Minnesota Hospital and have been treated during the past fifteen months. We have not grouped the cases into such distinct classes as "rheumatoid arthritis" (atrophic, proliferative) and "osteo-arthritis" (hypertrophic, degenerative). Most patients had multiple joint involvement and all had the common complaint of joint pain. Rigler, roentgenologist of the University Hospital, in a series of sixty-two consecutive cases, roentgenographed every joint in which there had ever been pain. In this group there was a high percentage of mixed types from the point of view of accepted roentgen diagnosis. The age of the patient may possibly modify the type of tissue reaction to streptococcic infection. Table 1 shows by decades the age range of the patients in our series.

TABLE 1.—*Age Distribution by Decades of Arthritic Patients*

| Age Group | Number of Patients |
|---|---|
| 0 to 9 | 1 |
| 10 to 19 | 9 |
| 20 to 29 | 32 |
| 30 to 39 | 51 |
| 40 to 49 | 103 |
| 50 to 59 | 92 |
| 60 to 69 | 58 |
| 70 and over | 10 |

Some people have the opinion that in many cases arthritis in older people is noninfectious. There are a number of older patients without symptoms in whom hypertrophic changes are noticed by roentgen examination. Such cases may not be of infectious nature. In our group of older patients complaining of joint pains the joint lesion was probably infectious in most instances. Evidence for this is that the incidence of subcutaneous nodules was greater in the older than in the younger patients in a series of 200 consecutive cases (table 2).

TABLE 2.—*Age Distribution by Decades of Patients with Subcutaneous Nodules*

| Decade | Number of Cases | Number with Nodules | Percentage of Nodules |
|---|---|---|---|
| 0 to 9 | 1 | 0 | 0 |
| 10 to 19 | 9 | 0 | 0 |
| 20 to 29 | 20 | 5 | 25.0 |
| 30 to 39 | 27 | 6 | 22.2 |
| 40 to 49 | 50 | 13 | 26.0 |
| 50 to 59 | 55 | 24 | 43.6 |
| 60 to 69 | 32 | 8 | 25.0 |
| 70 to 79 | 6 | 3 | 50.0 |

It is probable that some of our cases were not true examples of nonspecific chronic arthritis. Other forms of arthritis may simulate streptococcic arthritis. Gonorrheal and tuberculous arthritis are known to present a similar picture in some instances. Possibly the staphylococcus may be responsible for occasional cases, although there is little definite evidence that this is so.

### METHOD

Intravenous injections of a streptococcic vaccine were given. The organism used was isolated from the blood of a patient with rheumatic fever and pericarditis. This strain had been under cultivation for nine years and had been repeatedly used in previous animal experiments. It had been shown to cross agglutinate in high dilutions (1 : 50,000 and more) with a large percentage of strains of streptococci of rheumatic and chronic arthritic origin. This cross agglutination extends to strains of beta hemolytic streptococci as well as to viridans strains. This organism does not agglutinate spontaneously, is of low virulence, and is safe for intravenous injection.

The injections were given at weekly intervals for at least eight weeks in the average case, though there were some variations from this routine. After eight injections the interval was usually extended to two weeks for several more injections, and later extended to three or four week intervals, or treatment suspended for months. The extension of treatment was guided largely by clinical improvement and the height of the agglutination titer. The agglutinating titer appears to be a valuable indicator of the immunizing effect of vaccine therapy. An attempt was made to raise the streptococcic agglutinating titer to at least 1 : 6,400.

The initial dose used was 100 million killed organisms. This was increased by 100 million at each weekly injection, if no marked reaction had been experienced. If a disagreeable reaction followed the previous injection, the dose was usually kept at the same level in the following injection. The maximum did not usually exceed 800 million killed organisms, though this was exceeded in some cases in which reactions were minimal and the agglutination titer difficult to bring up to 1 : 6,400 or more. In some of the earlier cases treated, a maximum dose of 5 billion was given. The reactions were apt to be more severe with such a dosage, and there seemed to be no better clinical results, though possibly more prompt response. We have been careful to avoid other therapy in connection with vaccine treatment so that we might determine our results more fairly. The only medication advised has been 10 grains (0.65 Gm.) of acetylsalicylic acid following the injections to lessen or to avoid a reaction.

TABLE 3.—*Results of Therapy in Three Hundred and One Patients*

|  | Number of Cases | Per Cent |
|---|---|---|
| Definite clinical improvement | 233 | 77.4 |
| Questionable improvement | 19 | 6.3 |
| No improvement | 49 | 16.3 |

Reactions of some sort were experienced following about 50 per cent of the injections. There seemed to be a considerable amount of variation in the reaction in different individuals. A person might have reactions at one time and not at another. In more than 8,000 injections we have seen immediate symptoms suggestive of anaphylaxis (as seen following horse serum) in but one instance. In that case the patient experienced a transitory dyspnea and chest pain that quickly passed over and has not been present following other treatments. In most instances when a reaction was present the onset was from two to ten hours following treatment. The reactions usually consisted of chills of varying degree and duration, followed by fever. The chills lasted usually from one to two hours, and the fever had about the same duration. The fever when present was most often 100 to 101, though occasionally higher. In a few instances there was some severe aching at the time of reaction, especially in the back, though this was present in only an occasional case. Nausea, vomiting and diarrhea were sometimes present.

Patients quite frequently felt tired and ached the day following the injection, but more often there were no ill after-effects. We were unable to see any correlation between the improvement and the reactions experienced. We have tried to avoid reactions as much as possible in order not to incapacitate patients or discourage them in proceding with therapy.

Table 4.—*Criteria of Improvement*

| | Number of Cases | Per Cent |
|---|---|---|
| Joint pain (282 cases): | | |
| Decreased pain | 233 | 82.6 |
| Unchanged | 49 | 17.4 |
| Joint swelling (197 cases): | | |
| Decreased swelling | 160 | 81.2 |
| Unchanged | 37 | 18.8 |
| Joint motion: | | |
| Increased motion | 206 | 84.7 |
| Unchanged | 37 | 15.3 |

### RESULTS

Three hundred and sixty-five patients have received treatment. Three hundred and one patients of this group have received treatment adequate to determine the result of the therapy. To be considered adequate for results, patients must have reported following at least five injections. The sixty-four patients without adequate treatment consisted of those who discontinued treatment and those now under treatment who have not yet received five injections.

Clinical improvement was based on three general criteria: (1) decrease in pain, (2) decrease in joint swelling, and (3) increase in joint movement. An attempt has been made to discount the psychologic factor as much as possible. The fact that most of these individuals were outpatients and not on any other therapy did away with the objectionable factor of increased rest and change in surroundings, such as is encountered with hospital patients under any type of therapy.

Results of the different criteria for improvement are given in table 4, excluding the small number of questionable cases. In considering joint motion, improvement implied such factors as the ability to close the fingers more completely, to raise the hand to the head when unable to do so previously, to be able to extend the leg at the knee more completely, to be able to step up stairs when unable to do so previously, and other similar experiences. The most impressive factor in improvement was the high incidence in the decrease in joint swelling, as this could not be explained on a psychologic basis.

Table 5.—*Time of Beginning Definite Improvement*

| Number of Treatments | Number Improved | Percentage Improved | Total Percentage Improved |
|---|---|---|---|
| 1 | 13 | 5.6 | 5.6 |
| 2 | 39 | 16.7 | 22.3 |
| 3 | 46 | 19.7 | 42.0 |
| 4 | 47 | 20.2 | 62.2 |
| 5 | 34 | 14.5 | 76.7 |
| 6 | 18 | 7.7 | 84.5 |
| 7 | 13 | 5.7 | 90.2 |
| 8 | 8 | 3.4 | 93.6 |
| 9 | 11 | 4.7 | 97.4 |
| 10 | 2 | 1.3 | 98.7 |
| Over 10 | 2 | 1.3 | 100.0 |

A study was made of the number of injections required before definite clinical improvement was manifested. In many cases, questionable improvement might precede definite improvement by several weeks and in some instances the designation of the time of improvement was somewhat arbitrary. It is again to be noted that the treatments were usually given at weekly intervals. Table 5 shows the time of the beginning of definite improvement during the treatment. Nearly two thirds of the patients experiencing clinical improvement did so after five injections; nine tenths did so after seven injections. Very few patients reported clinical improvement if it was not present after ten treatments. Some of the unimproved patients received as many as twenty-five treatments without any change in the clinical course. In some instances the clinical improvement was very striking, while in others it was more gradual and less pronounced.

Improvement, once manifested, was usually fairly well sustained and increased while the patient was under therapy. There were some exceptions to this, however, as will be discussed in the correlation of clinical improvement and agglutinating titer. It is impossible to predict improvement in any individual. In general, the results were better in earlier and less severe cases, although we have had some striking examples of improvement in severe cases of many years' standing. Some of these patients observed over a period of months have made a marked gain in weight and have shown definite hypertrophy in previously atrophied muscle groups. Contrary to the experience with subcutaneous vaccines, there has not been a definite aggravation of the arthritic process in any case.

Table 6.—*Initial Agglutination Titer in Chronic Arthritis (Three Hundred Cases)*

| Dilution | Number | Per Cent |
|---|---|---|
| 1:0 | 30 | 10 |
| 1:50 | 33 | 11 |
| 1:100 | 67 | 22 |
| 1:200 | 73 | 24 |
| 1:400 | 64 | 21 |
| 1:800 | 25 | 8.3 |
| 1:1,600 | 6 | 2 |
| 1:3,200 | 1 | 0.3 |
| 1:6,400 | 1 | 0.3 |

### AGGLUTINATING TITER AND VACCINE THERAPY

In correlation with the vaccine therapy, agglutinating titers were determined with the organism with which the chronic arthritic patients were treated. Agglutinating titers were obtained before therapy was instituted in 300 cases of chronic arthritis (table 6). The greatest percentage showed the highest agglutinating titer to be 1:200. There was no marked difference in the agglutinating titer of normal individuals and chronic arthritic patients except for the tendency of a small number of titers to be at a higher level in chronic arthritic patients. For the most part the slightly higher titers in the cases of chronic arthritis were obtained in those with a more active involvement. It must be borne in mind that streptococcic infections are common. Few individuals can be considered "normal" in relation to streptococcic infection. We did not observe any more favorable response to treatment in persons with high initial titers than in cases with initial titers of 1:0 or 1:50. Tables 7 and 8 show the relation of the heights of the agglutinating titers to clinical improvement.

Intravenous streptococcic vaccine therapy elicited a definite rise in the agglutinating titer of the serum of most treated patients. The maximum dilution in which agglutination occurred was 1:100,000. Such a titer was obtained in one patient. Several had titers of 1:50,000 and many of 1:25,000. A definite correlation has been observed between the height of [illegible] and the clinical improvement in [illegible] who have shown marked improvement after one or two injections have in most instances shown a corresponding elevation in the agglutinating titer. It is difficult to place any definite level of titer as that at which improvement should be manifested, though in general most patients felt definitely better when the titer was 1:6,400 or higher. Clinical improvement was found in some instances with an agglutinating titer as low as 1:3,200. In a few cases, individuals improved with a lower titer.

Once raised, the agglutinating titer tends to remain at a high level, but occasionally it may drop back unexpectedly. Acute respiratory infections and too large doses, or too frequent treatments may be factors in reducing the agglutination titer. If eight or ten injections have been given and the titer is 1:6,400 or greater and the patient clinically improved, it seems advisable to suspend treatment for several months or until there is a recurrence or aggravation of the joint symptoms. Agglutinating titers should be checked at monthly intervals, if possible, after suspending treatment. Titers will often remain at a high level for months. With recurrence or aggravation of symptoms, only a few small injections are usually sufficient to restore the titer to a high level with a corresponding clinical improvement. A number of patients in our series have been followed for from two to eight months without therapy and with observation of the agglutinating titer and clinical improvement (table 9).

Table 7.—*Distribution of Maximum Agglutination Titer in One Hundred and Eighty-Eight Improved Treated Arthritic Patients*

| Titer | Number | Percentage | Total Percentage |
|---|---|---|---|
| 1:800 | 4 | 2.1 | 2.1 |
| 1:1,600 | 9 | 4.7 | 6.8 |
| 1:3,200 | 27 | 14.3 | 21.1 |
| 1:6,400 | 54 | 28.8 | 49.9 |
| 1:12,800 | 71 | 37.8 | 87.7 |
| 1:25,000 | 20 | 10.6 | 98.3 |
| 1:50,000 | 3 | 1.7 | 100.0 |
| 1:100,000 | 0 | | |

The agglutination titer was considered in unimproved treated patients. Apparently two types of patients are seen in the unimproved group. The first type are those in whom it is difficult to bring up the agglutinating titer even though large repeated doses of vaccine are given. It is of interest that the maximum titer in the improved group was less than 1:6,400 in 21.1 per cent of the cases (tables 7 and 8), while in the unimproved group the titer was less than 1:6,400 in 40.5 per cent of the cases. Some of the unimproved patients, however, have had a high titer sustained over a period of several months.

As a further check on the significance of the agglutinating titer, the bactericidal power of the blood for streptococci was determined [14] by using the method of Sutliff and Rhoades,[15] who determined the bactericidal power of the blood for pneumococci in patients with lobar pneumonia. We tested the blood of normal individuals and of untreated and treated arthritic patients. The blood from treated patients, with an agglutination titer of 1:6,400 or more, was found to have a much higher bactericidal power against the streptococci used in the vaccine than did the blood of normal patients, untreated arthritic patients, or treated patients with low agglutinating titers.

### CONTRAINDICATIONS TO VACCINE THERAPY

We have not treated pregnant women because of the frequency with which abortion has been produced in pregnant hypersensitive rabbits receiving intravenous injections of streptococci. We considered it inadvisable to administer intravenous vaccine to patients with chronic arthritis who also had glomerulonephritis. In acute phases of arthritis with persistent fever the dosage has been reduced or therapy postponed until the acute febrile period has ended.

Table 8.—*Distribution of Maximum Agglutination Titer in Thirty-Seven Unimproved Treated Arthritic Patients*

| Titer | Number | Percentage | Total Percentage |
|---|---|---|---|
| 1:100 | 1 | 2.7 | 2.7 |
| 1:200 | 0 | 0.0 | 2.7 |
| 1:400 | 2 | 5.4 | 8.1 |
| 1:800 | 3 | 8.1 | 16.2 |
| 1:1,600 | 1 | 2.7 | 18.9 |
| 1:3,200 | 8 | 21.6 | 40.5 |
| 1:6,400 | 12 | 32.4 | 72.9 |
| 1:12,800 | 5 | 13.5 | 86.4 |
| 1:25,000 | 5 | 13.5 | 100.0 |

### COMMENT

The results of intravenous streptococcic vaccine treatment in 365 cases of chronic arthritis and important considerations developing during the course of the treatments are discussed in this paper.

In considering the clinical results, it has been borne in mind that arthritis is a disease frequently showing improvement and presenting exacerbations of symptoms without therapy. This factor has been considered in estimating clinical improvement in our patients. When improvement has been definitely manifested we have found that, almost without exception, no such degree of spontaneous improvement had been present in the past or with other types of therapy. Our previous experience with patients with well established chronic arthritis has been that, while occasionally definite spontaneous improvement might occur, there was rarely a degree of improvement comparable to that frequently shown by our patients receiving intravenous vaccine therapy. The degree of improvement that may be obtained in any given case varies with the degree of permanent damage of the joint. It is, of course, impos-

Table 9.—*Duration of Elevated Agglutination Titer and Clinical Improvement Following a Course of Therapy and Without Further Injections*

| Patient | Time Since Treatment | Titer After Course of Treatment | Titer After Interval | Improvement Sustained |
|---|---|---|---|---|
| 1 | 10 months | 1:100,000 | 1:6,400 | Never improved |
| 2 | 8 months | 1:6,400 | 1:6,400 | + |
| 3 | 7½ months | 1:6,400 | 1:3,200 | + |
| 4 | 7 months | 1:25,000 | 1:25,000 | + |

sible to have much effect on an ankylosed joint or to do away with preexisting fibrous adhesions. Patients with permanent crippling lesions may obtain relief from pain and subsidence of joint effusion when present, but cannot have replacement of a destroyed synovial membrane or absorption of fibrous scar tissues. Many patients, however, are crippled with only a moderate degree of permanent joint destruction and in such cases much practical benefit may be derived from therapy. A number of such patients have been able to resume work in a relatively short period of time when unable to do so previously.

The intravenous method was used because it met the demands found necessary by previous experiments and observations for the development of a protective immunity without the handicap of a hypersensitive state. Definite clinical improvement occurred in about 80 per cent of the adequately treated patients. This improvement was indicated by (1) decrease in pain, (2) decrease in swelling, and (3) increase in joint motion. The degree of improvement bore no relation to the degree of the reaction occurring at the time of injections. As a rule, several injections were necessary before improvement was observed.

The streptococcic agglutinating titer rose with the course of treatment. A titer of 1:6,400 or more bore a close correlation to clinical improvement observed in the patient. The whole blood of treated patients having such a titer was found by experiment to have a much greater bactericidal power against streptococci than the blood of untreated patients. The agglutinating titer proved to be a reliable laboratory indicator of the degree of protective immunity possessed by the treated patients.

These experiments have not been in effect long enough to draw definite conclusions concerning the duration of clinical improvement and a sustained high agglutination titer. In a few cases both the improvement and a high agglutination titer have been sustained for as long as eight months.

A control series has not been compared with the treated group. It is known that many arthritic patients, without therapy, show variable symptoms at different times. Our results do not justify a claim of a cure for chronic arthritis, but it seems that patients vaccinated intravenously with streptococci show improvement in a higher percentage than is seen in patients without therapy or in those receiving other forms of therapy.

### CONCLUSIONS

1. Eighty per cent of chronic arthritic patients treated intravenously with a streptococcic vaccine were clinically improved.
2. The degree of improvement bore no relation to the degree of reaction following the injection.
3. Improvement was manifested in most cases after five weekly injections.
4. The agglutinating titer of the patients' blood rose during the course of treatment. Improvement as a rule did not take place until the titer had risen to 1:6,400 or more.
5. Treated patients' serums which agglutinated streptococci in dilutions of 1:6,400 or more had a much higher bactericidal power for streptococci than the serums of untreated chronic arthritic patients.
6. The height of the agglutinating titer in most cases seems to be a reliable indicator of the degree of protective immunity to streptococci possessed by the treated patient.

# TREATMENT OF RHEUMATIC FEVER PATIENTS WITH AND WITHOUT SALICYLATES

## A CLINICAL AND ELECTROCARDIOGRAPHIC STUDY

A. M. MASTER, M.D.
AND
ALFRED ROMANOFF, M.D.
NEW YORK

Competent investigators[1] have shown that the salicylates are not specific in rheumatic fever but rather that they are merely extremely efficient analgesics and antipyretics for this disease. There is still, however, a belief that the salicylates prevent cardiac complications and shorten the duration of the illness. In a study of fifteen patients, Hanzlik[2] found that salicylates shortened the hospital stay and stated that the sequelae of pericarditis and effusions appear to be less and that the general circulatory result is better than without treatment. White[3] states that if the salicylates are used, much heart disease can be averted. Levy and Turner,[4] using the electrocardiogram, found that salicylates improved faulty conduction between the auricles and the ventricles. To such an extent has this feeling progressed that Kerley[5] advises its administration to children predisposed to heart disease, and Epstein[6] recommends its routine use in the form of salicylic acid fruit juices for all children, beginning in the second year of life.

Opposed to the foregoing group is Miller,[1] who culled the literature and found that 1,907 patients receiving salicylates had an average hospital stay of 33.28 days and that 1,600 patients not receiving salicylates remained in the hospital for an average of 33.6 days. Ehrström and Wahlberg[1] reviewed 51,811 cases and were of the opinion that heart failure, valve disorder and polyarthritic complications were not diminished by the administration of salicylates. Carr and Reddick,[7] on the basis of electrocardiographic tracings, concluded that salicylates were without effect in conduction disturbances, "neither causing them, nor tending to control them." Wyckoff, DeGraff and Parent[8] also found no evidence that salicylates affect the auriculoventricular conduction time.

Although a review of the work of the early investigators[9] covers thousands of cases, a close analysis shows

of how little use most of it is. Murmurs, endocarditis and pericarditis were often considered complications, whereas we now know that a carditis is an essential part of rheumatic fever. Besides, clinicians differ on what constitutes a cardiac complication, and if statistics are to be of help, one must compare patients treated with and without salicylates by the same investigator. This was usually not the case.

In order to clarify the divergent views and because we feel that the practitioner of medicine still believes that the salicylates prevent cardiac complications and shorten the duration of hospital stay, we instituted the following investigation: Rheumatic fever patients were treated alternately with and without salicylates. Thirty of the patients served as controls and received no salicyl compounds whatever. To them was administered either one-half grain (0.03 Gm.) of codeine or one-fourth grain (0.015 Gm.) of morphine sulphate when the joint symptoms were severe or when the patients were restless or uncomfortable. The drugs were repeated whenever necessary, but never given in toxic doses. In the dosage prescribed by us, morphine [10] does not alter the electrocardiogram. Patients occasionally received bromides, acetphenetidin and acetanilid. The thirty-three rheumatic fever patients were given daily doses of salicyl compounds either orally, by rectum, or both. Adequate doses were always given, i. e., from 120 to 180 grains (from 8 to 12 Gm.) a day was the average minimum, and twice this amount was not unusual. Many of the patients of this group received thousands of grains of salicylates during their hospital stay. No one received digitalis or any other drug that produces changes in the electrical tracings. Electrocardiograms were taken daily with the patient always in bed. The same conditions prevailed for the two groups. They were chosen alternately and treated by the same physicians and nurses.

Table 1.—*Clinical Comparison*

| | Number of Patients | Average Age | Males | Females | Average Hospital Stay | Deaths |
|---|---|---|---|---|---|---|
| Control group.. | 30 | 25 | 18 | 12 | 46.2 days | 1 |
| Salicylate group | 33 | 26 | 18 | 15 | 42.0 days | 1 |

| | Control Group | Salicylate Group |
|---|---|---|
| Monocyclic type | 26 | 27 |
| Polycyclic type | 4 | 6 |
| Acute pericarditis | 11 | 9 |
| Pericarditis with effusion | 3 | 3 |
| Rheumatic aortitis | 1 | 0 |
| Pneumonic infiltration | 3 | 3 |
| Pleural effusion | 4 | 4 |
| Pulmonary infarction | 2 | 0 |
| Acute glomerulonephritis | 0 | 1 |
| Thrombophlebitis (left internal saphenous vein) | 0 | 1 |
| Chronic purulent otitis media | 0 | 1 |
| Jaundice | 0 | 1 |
| Visceral manifestations (diarrhea and abdominal pain) | 0 | 1 |
| Toxic psychosis | 0 | 1 |
| Erythema annulare | 0 | 1 |
| Urticaria | 2 | 0 |

Table 1 shows that there were thirty-six males and twenty-seven females, with an average age of 26 years, the youngest being 13 and the oldest 53. The average hospital stay for the control group was forty-six days and for the salicylate series forty-two days. This is as near an accord as one can possibly expect, for the average deviation of the number of days in the hospital is large, the time of hospitalization ranging from as short a time as 9 days to as long a period as 108 days. In each group one death occurred. A study of the monocyclic and polycyclic types of the disease discloses that the two groups were parallel. Acute pericarditis occurred in eleven patients in the control group and in nine in the salicylate series. In each division, three patients developed effusion in the pericardial sac. A rheumatic aortitis was diagnosed in one patient, pulmonary infarction in two, and urticaria in two patients of the control group. A "pneumonic infiltration" was proved by teleroentgenogram in six patients, and a pleural effusion in four, equally distributed between the two groups. Acute glomerulonephritis, a left internal saphenous vein thrombophlebitis, a chronic purulent otitis media, jaundice, diarrhea and abdominal pain, an erythema annulare, and a toxic psychosis were found once each in different patients of the salicylate group only.

Table 2.—*Changes in Rhythm and in Electrocardiographic Waves*

| | Control Group | Salicylate Group |
|---|---|---|
| Number of patients | 30 | 33 |
| Average age | 25 | 26 |
| Myocardial involvement (electrocardiograms) | 30 (100%) | 33 (100%) |
| Change in Rhythm | | |
| Tachycardia | 21 | 22 |
| Bradycardia | 6 | 7 |
| Sinus arrhythmia | 6 | 8 |
| Sino-auricular block | 3 | 2 |
| Auricular premature beats | 2 | 4 |
| Ventricular premature beats | 1 | 2 |
| Nodal tachycardia | 1 | 0 |
| Nodal rhythm | 0 | 1 |
| Interference sinus and nodal rhythm | 0 | 2 |
| *Paroxysmal auricular fibrillation* | 1 | 1 |
| Paroxysmal auricular flutter | 1 | 1 |
| Change in Electrocardiographic Waves | | |
| P-R (0.20 second) | 5 | 3 |
| P-R (0.21 second and more) | 16 | 17 |
| Total P-R | 21 | 20 |
| Dropped beats | 2 | 1 |
| R-S-T abnormalities | 26 | 27 |
| Flat T waves | 3 | 4 |
| Inversion T waves | 10 * | 8 † |

* Nine cove-plane shape.
† Five cove-plane shape.
‡ One cove-plane shape.

It would be a difficult and useless matter to weigh one complication against another. It is clearly evident that the control group fares as well as the salicylate group in regard to cardiac and other visceral complications. It is only when one considers subjective relief of pain that the control group does not do as well perhaps as the patients who received large doses of salicylates. The defervescence in the latter group occurred somewhat earlier, and the joint immobility and pain seemed to disappear more promptly.

The electrocardiograph [11] is perhaps the most practical and accurate means one has for an investigation of myocardial involvement. Table 2 presents figures that are as decisive as those in the clinical summation.

A.; Sacks, Bernard, and Libman, Emanuel: The Disturbances of the Cardiac Mechanism in Subacute Bacterial Endocarditis and Rheumatic Fever, Am. Heart J. **2**: 356 (April) 1927.

The electrocardiographic abnormalities are arranged according to (*a*) abnormal rhythms and (*b*) changes in the electrical waves; i. e., abnormalities of the auricular waves (P waves), of auriculoventricular conduction (P-R intervals) and of the ventricular portion of the electrocardiogram (Q-R-S, R-S-T and T waves).

There was a 100 per cent involvement of the heart in both the control and the salicylate group. Not a patient's myocardium escaped damage, no matter whether or not salicylates were administered. We have been conservative in our interpretation of what constitutes electrocardiographic evidence of myocardial involvement and have included only sino-auricular block, nodal rhythm, interference of sinus and auriculoventricular nodes, paroxysmal auricular fibrillation or flutter, auriculoventricular conduction time of 0.21 second or more, dropped beats, definite R-S-T deviations, inversions of T waves in leads I and II only, and transient but distinct widening, notching or slurring of the Q-R-S group.

Again, the comparison of the incidence of the electrocardiographic changes in the two groups is surprisingly equal. Although the figures vary here and there, the difference is very slight and well within limits of error. The totality of changes in each group is practically the same. The increased auriculoventricular conduction is twenty-one in the control group, twenty in the salicylate; the T wave changes fifteen in the control, and fourteen in the salicylate; the R-S-T changes twenty-six in the control, and twenty-seven in the salicylate. These are the changes commonly searched for with the electrocardiogram for evidence of myocardial involvement.

The auriculoventricular conduction time changes were as variable in the group receiving salicylate therapy as in the control group. The defective conduction (i. e., increased P-R interval) might return to normal and then become impaired again. Neither the extent nor the duration of the conduction defect was materially different. We do not wish to go into detail on this subject, as other authors[12] have already proved this point.

## SUMMARY

Thirty-three patients who received adequate salicylate therapy and thirty who served as controls were compared clinically and as to detailed electrocardiographic evidence of myocardial involvement. No essential difference was discovered.

In the rheumatic fever patients, whether or not salicylates were administered, a 100 per cent involvement of the myocardium was found. The duration of hospital stay in the control group was forty-six days; in the salicylate group, forty-two days. One death occurred in each group. Polycyclic course, occurrence of pericarditis with or without effusion, and involvement of the lungs and other viscera were practically the same in the two groups.

The electrocardiographic changes indicative of myocardial involvement revealed a surprising coincidence of changes in the two groups, qualitatively and quantitatively.

There is no evidence that salicylates prevent cardiac complications or shorten the duration of hospital stay, although they are at present the most efficient antipyretics and analgesics for the treatment of acute rheumatic fever.

## THE EFFECTIVENESS OF PENTOBARBITAL IN ANTIDOTING STRYCHNINE POISONING IN THE RABBIT

O. W. Barlow, Ph.D., Cleveland

Following the report of Dawson and Taft[1] in which several barbitals were shown to antagonize effectively the fatal reaction of the rabbit to from 1 to 1½ lethal doses of strychnine, an attempt was made to adapt the results of their study for inclusion in our course in pharmacodynamics. The observations of these authors in relation to pentobarbital were confirmed; the other members of the group were not tested. The ease with which the antagonism may be demonstrated and the remarkable protective effect of pentobarbital against strychnine poisoning (up to thirty-five times the minimum lethal dose) appeared to merit publication of a representative protocol and a summary of the results obtained with various dosages of the alkaloid simply as an extension of the studies of Dawson and Taft. Recently, and subsequent to completion of these observations, Swanson[2] observed that amytal antidotes approximately 10 lethal doses of strychnine in the rabbit; and Haggard and Greenberg[3] reported that apomorphine and phenobarbital

* The one fatality was due to overdosage with pentobarbital.

† One animal killed with initial injection of pentobarbital.

‡ One died fifty-two and the other ninety minutes after the injection of strychnine. Overdosage with pentobarbital was considered the primary cause of death.

§ Animals receiving this dose are very difficult to control. The two surviving animals required artificial respiration for varying periods owing to overdosage with a barbital derivative.

‖ This dose is too depressant. Strychnine and pentobarbital produce an additive depression of respiration.

*Typical Protocol—Strychnine Antagonism by Pentobarbital Sodium*

Rabbit, albino; weight, 2 Kg.
9:14 a. m.: Injected 36 mg. of strychnine sulphate (as 2 per cent solution) subcutaneously, equivalent to 30 times the lethal dose.
9:16½: Moderate convulsive movements.
9:18: Very strong tetanic convulsion.
9:18½: Pentobarbital (0.5 cc., 5 per cent solution), 12.5 mg. per kilogram by vein produced complete relaxation.
9:22: Moderate tetanic convulsions; 12.5 mg. per kilogram by vein (pentobarbital).
9:35: Moderate tetanic convulsions; 12.5 mg. per kilogram by vein (pentobarbital).
9:53: Slight convulsive twitch; 12.5 mg. pentobarbital per kilogram intramuscularly; deep anesthesia.
11:00: Animal sneezes occasionally; slight convulsive movements.
11:05: Animal sneezes repeatedly; slight convulsive movements; injected 12.5 mg. pentobarbital per kilogram by vein.
12:07 p. m.: Animal sneezes; convulsive movements quieted by pentobarbital (12.5 mg. per kilogram) by vein.
1:25: Strong convulsions; same dose of pentobarbital by vein.
2:50: Sneezing results in [illegible]
2:55: Injected 12.5 mg. [illegible] by vein.
4:00: Reflex excitability [illegible] up.
5:15: Injected a unit dose of pentobarbital by vein.
8:00 a. m.: Drowsy; lies on side but is awake.
10:30: Apparently normal; hops about and eats.
This animal was in good condition thirty days later.

effectively antagonize several lethal doses of strychnine in the rat and dog. Pentobarbital from a practical standpoint offers certain advantages over amytal or phenobarbital in that, owing to its short duration of action, small effective doses may be repeated at intervals as required by the severity of the symptoms. This factor of safety is quite important following the administration of very large doses of strychnine.

The convulsant and lethal effects of strychnine administered subcutaneously to rabbits in doses of 12 mg. or less per kilogram are easily combated after the development of convulsions by means of pentobarbital by vein in doses of from 6 to 15 mg. per kilogram and repeated at intervals at first in from three to five minutes and later in from ten to thirty minutes, as required by the recurrence of convulsions. However, control of the convulsions following the administration of larger doses of the alkaloid, i. e., up to 21 mg. per kilogram (thirty-five times the minimum lethal dose taken as 0.6 mg. per kilogram) becomes increasingly difficult as the depressant effects of strychnine on the medullary centers are additive with those of effective doses of the hypnotic, and a slight overdose with pentobarbital tends to paralyze the respiratory center. Under such conditions the institution of artificial respiration was usually followed after a variable period by the resumption of spontaneous respiratory movements; but the maximal dose of strychnine that may be effectively antidoted with pentobarbital with a fair chance of success, i. e., the ultimate recovery of 50 per cent of the animals, is probably 21 mg. per kilogram.

Pentobarbital and strychnine within limits were mutually antagonistic in that from 1½ to 2 lethal doses of the barbiturate were effectively antidoted by small repeated doses of strychnine. A similar relationship between phenobarbital and strychnine has been observed by Haggard and Greenberg.

On the basis of these experiments, the suggested safe dose of pentobarbital for an adult man suffering from strychnine poisoning would be one-tenth grain (6 mg.) per pound for the first dose and if convulsions recur, one-half this amount (one-twentieth grain [3 mg.] per pound) for each succeeding dose. Caution should be used if more than four injections are given during the first two or three hours.

### CONCLUSIONS

1. Pentobarbital in small repeated doses by vein effectively antidotes up to thirty-five times the minimum (subcutaneous) lethal dose of strychnine in the rabbit.
2. Strychnine within limits is mutually antagonistic with pentobarbital and effectively antidotes from 1½ to 2 lethal doses of the barbiturate.

## DR. BOOT'S NONSURGICAL TREATMENT FOR SWALLOWED FOREIGN BODIES

### (A POSTHUMOUS REPORT ON THE METHOD)

L. W. SAUER, M.D., EVANSTON, ILL.

On Sept. 1, 1927, Mary J., aged 7 years, accidentally swallowed a twenty-five cent piece (quarter-dollar). Its passage into the stomach was accompanied by much discomfort and pain. The pain was most intense below the sternum. After the coin passed the cardia, relief was instantaneous. Fluoroscopic examination about two hours later showed the coin in the fundus of the stomach. As there were no symptoms, I asked the mother to notify me if any distressing symptoms arose; otherwise, to report when the coin was passed. Three days later, fluoroscopic examination showed that the coin had not left the fundus. There were no symptoms. The child had eaten three hearty meals each day and had had a daily evacuation. Six days after the accident, the coin was still in the fundus. Nine days after the accident, fluoroscopic examination showed the coin still in the fundus. The mother was now quite concerned but, owing to the absence of symptoms, was willing to wait longer. On the following day I spoke to a noted abdominal surgeon about the case. He felt certain that the coin was too large to pass the pylorus. He recommended surgical removal. I then conferred with the late Dr. George W. Boot, who had on numerous occasions removed foreign bodies from the trachea, bronchi and lungs of children. He said: "Have the child eat a good-sized bowl of mixed vegetables—cabbage, green beans and celery. The vegetables should not be cooked soft, and should be swallowed without much if any mastication. Wash them down with a little water if necessary. Give no laxative." His orders were carried out without delay. Within twelve hours after the first bowlful of vegetables had been eaten, the coin was passed by rectum. Dr. Boot suggested, at the time, that the case be reported. In the interim, seven other children have been treated by the same method for swallowed foreign bodies—open safety pins (one rather large, two medium sized), three cases; five-cent piece (nickel), one case; small pocket knife, one case; tack, one case; penny, one case. Doubtless many small objects will pass through the intestine without resort to the coarse vegetable diet, but the prompt passage of the twenty-five cent piece, which had remained in the stomach for ten days, warrants a trial in any uncomplicated case of swallowed foreign body.

636 Church Street.

# Special Article

NOTE.—The following article is one of a series on the Present Status of the Knowledge of Vitamins, prepared under the auspices of a committee composed of Morris Fishbein, chairman, Lafayette B. Mendel and Julius Hess, representing a joint committee of the Council on Pharmacy and Chemistry and the Committee on Foods. These articles have been considered by the Council on Pharmacy and Chemistry and by the Committee on Foods and are published under their auspices. The opinions expressed are those of the authors and not necessarily the opinions of the Council on Pharmacy and Chemistry or the Committee on Foods.—ED.

## VITAMIN A

LAFAYETTE B. MENDEL, PH.D., SC.D.
Sterling Professor of Physiological Chemistry, Yale University
NEW HAVEN, CONN.

The story of the discovery of the significance of the hitherto unidentified dietary essential at present designated as vitamin A is of unusual interest to students of medicine. It helped to implant more firmly the idea that diseases may be due to deficiencies. Thus, the "Report on the Present State of Knowledge Concerning Accessory Food Factors (Vitamines)" prepared for the British Medical Research Committee in 1919 points out that:

> Disease is so generally associated with positive agents—the parasite, the toxin, the *materies morbi*—that the thought of the pathologist turns naturally to such positive associations and seems to believe with difficulty in causation prefixed by a *minus* sign. Even in connection with deficiencies arising within the body there is or was a similar tendency. When the importance of internal secretions was first recognized there seemed to be much hesitation in believing that symptoms might be frankly due to their failure. When each fresh internal secretion was described there was always an effort to show that its function was to "neutralize" some, always hypothetical, toxic substance. Symptoms, on this view, were due to the unmasking of a deleterious agent rather than to simple deficiency in a normal and necessary agent. To distinguish between these two possibilities was of course a scientific duty; but, at any rate in the earlier literature of internal secretions, a bias against the simpler view interfered with the fair interpretation of experimental results. So in connection with the newer conception of disease as due to dietetic deficiencies.

One of the foremost investigators of nutrition of the past generation, Carl Voit, remarked that the ideal plan for studying the relative dietary values of the ingredients of our food intake would be to feed the

---

From the Department of Pediatrics, Northwestern University Medical School.

pure foodstuffs—protein, fat, sugar, starch and inorganic compounds—and observe the effects thereof. He insisted that neither man nor experimental animals would be likely to tolerate such unpalatable rations for any length of time as they do the usual foods of daily life; but he added his belief that if the purified proximate principles were actually fed as proposed, the outcome would not be essentially different from our experience with naturally occurring food mixtures.

The ideal experiment that Voit had postulated was undertaken by various investigators, always without success. Milk, which was known to be an excellent food, contains protein, fat, carbohydrate and inorganic salts. The attempts to support animals on mixtures of isolated milk protein, plenty of fat and carbohydrate to supply the energy requirement, and the inorganic elements present in milk, invariably resulted in failure. As small additions of certain "natural" foods to such inadequate rations were effective in promoting nutrition, it gradually became apparent that substances other than the familiar "proximate principles" or foodstuffs also are indispensable. Such substances were presently designated "vitamins."

### DISCOVERY AND OCCURRENCE OF VITAMIN A

Many attempts have been made during the past two decades to track these "accessory food substances" to their origin. Part of the story is revealed in other papers in this series. In 1913, several American investigators discovered that the inadequate diets, composed of mixtures of isolated foodstuffs and simulating milk in their proximate composition but having the fat represented by lard, could be converted into wholesome mixtures by merely replacing the lard with milk fat. As one reviewer remarked:

> Lard, obtained from swine, is as much of a fat as butter fat or olive oil, or any other of the several varieties of fats and oils on the market. The differences among the fats are largely due to differences in quantity of the three fatty acids they usually contain. The differences can never be as profound as those between proteins, formed as the latter are from eighteen different amino-acids. When, therefore, our investigators found the substitution of lard for butter fat to produce loss of weight and general decline, they attributed the deficiency of lard not to the fat itself but to a *something* accompanying the butter fat and not the lard.

This unidentified "something" still bears the designation of vitamin A, though there can be little doubt that the chemical identity of the indispensable factor in nutrition represented thereby will sooner or later be ascertained, so that it can be labeled in accord with the dictates of modern chemical nomenclature. The prevailing air of mystery and magic about the subtle nutritive potencies of the vitamins will be dispelled when their exact chemical nature is clearly revealed. One may recall how the discovery of the composition of the thyroid hormone, its relation to iodine, and the actual synthesis of a potent product has clarified the atmosphere of uncertainty regarding many aspects of thyroid malfunction.

Vitamin A is widely distributed in nature in products of both animal and plant origin that are used as food by man and animals. In all these instances the potent constituent has been found to be associated with fats or fatlike substances. It is removed from its sources by extraction with fat solvents, such as ether, chloroform, hot alcohol and other commonly used organic solvents. This does not mean, however, that vitamin A is a true fat, that is, a glyceride of a fatty acid, or even a fatlike ester. Its association with fats in nature is presumably due to comparable solubilities, as is the case with many higher alcohols, sterols, and certain pigments in nature.

### DETECTION OF VITAMIN A

The detection and quantitative determination of vitamin A depends at the present time on biologic methods of examination. For such purposes the use of the albino rat (Mus norvegicus-albinus) or the "hooded" types has become the classic procedure, although other species of animals also are responsive to the tests. Direct chemical procedures have been suggested and will be referred to later. Their actual value and dependability are much debated and probably will remain so until more is known about the real chemical nature of vitamin A. Briefly outlined, the biologic tests depend on observing the nutritive behavior and any abnormal symptoms of animals subsisting on rations in which the presence or absence of some source of vitamin A is the only variable factor. This implies that the diet must contain *all* the other essentials—adequate protein and other energy-yielding nutrients, suitable inorganic components, other vitamins and water—without which nutritive disaster is bound to occur. Consequently, success or failure will depend primarily on the presence or lack, respectively, of vitamin A. An entirely adequate regimen will permit not only maintenance of the adult animal but also proper breeding, including healthy pregnancy, parturition, lactation and proper growth of the young. Ordinarily the biologic tests are twofold in character: preventive tests, in which the inclusion of the product under investigation with respect to vitamin A in the diet will prevent the onset of the symptoms of deficiency, and curative tests, in which the addition of the product may restore to physiologic well being animals that show the characteristic signs of nutritive decline on so-called otherwise adequate basal vitamin A-free rations.

### CHARACTERISTICS OF AVITAMINOSIS

Before referring to more specific details of such tests, it is desirable to describe the evidences of a deficiency of vitamin A in the diet. In young animals the interruption of growth is one of the earliest signs. This is, however, a manifestation of practically every type of deficiency. The "law of the minimum" has become so firmly established for nutrition that one expects that the need of any essential will impede growth in animals as well as in plants, in cases in which the power is lacking to synthesize de novo the missing factor. Consequently it has been fortunate for the investigator that other, more specific evidences of deficiency of vitamin A have been discovered.

The first outstanding sign that "all is not going well" in the bodily functions was described in 1913 by Osborne and Mendel. They noticed occasional cases of eye disease that they were at first inclined to attribute to accidental infection. Attempts that were made to relieve such conditions by the local application of antiseptics, notably silver-protein combinations, were not successful. Presently, however, it became apparent that, despite the ready possibility of infection throughout a large colony of animals kept under the same hygienic conditions, the eye disorders did not occur when good nutritive conditions were secured by suitable diets. The views of ophthalmologists in regard to the etiology of the type of eye disease, designated among other names by the terms keratomalacia and xerophthalmia, have changed from time to time under the influence of the prevailing tendencies in the study of pathology. Thus, Goldschmidt has pointed out that long ago a relationship between nutritive disturbances and ophthalmia seemed to be established. With the progress of modern bacteriology, this aspect of the subject became overshadowed by the assumption that the ophthalmia is primarily an infection for which various micro-organisms have been held responsible.

A characteristic ophthalmia is an almost unfailing manifestation of a diet lacking in vitamin A; it is promptly cured if some source of this food factor is included in the diet before bacterial invasion of the diseased ocular tissues leads to irreparable damage. In the case of the rat an excellent description of the common sequence of symptoms in A-avitaminosis has been given by Gudjónsson:

> The first sign of this condition to be noticed by a trained eye is that the hairy coat is no longer as smooth as it should be in a normal animal. At the same time the rat begins to become emaciated; it grows lean and wastes away in flesh. Its lines are no longer soft and curved as they are normally in a healthy rat. The rat is no more as agile as it used to be; its movements are no longer marked by the creeping suppleness that is so characteristic of the rat. Its movements begin to be incoordinate. The silky feet with the pink soles become rough and scaly, skinny and bony. The tail is thinner and the caudal vertebrae are felt as sharp edges under a paper cover. The rat begins to be negligent of cleanliness. There are remnants of food smeared about its mouth and sticking between its teeth; there are crumbs between its toes. Its eyes begin to be less protruding and apparently smaller. The voice becomes hoarse; complete aphonia is not infrequent. Other particular signs are rare in the first stage of A-avitaminosis. By this time the rat has grown accustomed to the diet, and intestinal irregularities are extremely rare. Then comes the clinical manifestation of xerophthalmia. Often this lesion progresses at a surprising rate. One day, perhaps, there may be noticed a little bit of sanguinolent secretion in the inner canthus, and it looks as if there are fewer cilia in the eyelashes (the cilia are sticking together). The next day one may find copious secretion, serous, purulent or sanguinolent; the eyes are almost shut, and the cornea is beginning to become opaque. The conjunctiva is injected and inflamed. In two or three days there may thus have developed a suppurative panophthalmia. The eyelids are swollen and almost glued together with purulent matter.
>
> By this time the rat has ceased to gain in weight and has perhaps even begun to lose weight. Not infrequently, rhinitis comes on. There is a profuse discharge from the nose, and the respiration is accompanied by râles; the nasal secretion is sometimes blood tinged. The sense of smell, which seems particularly well developed in the normal rat, now appears to be less acute. For these animals have some difficulty in finding their food; but this may perhaps also be due to their loss of vision.
>
> In the last part of the foreperiod and in the severe stages of A-avitaminosis, about one third of the males are suffering from priapism. By this time the lymph glands of the neck are enlarged and can be made out on palpation. These inflamed lymph glands, in which abscess formation often takes place, may become as large as peas, or larger. The abscesses do not infrequently perforate, and they rarely heal, unless the rat is supplied with vitamin A, but persist as fistulas. At this time, too, the rats often have hematuria. In the last stage of the disease, diarrhea is encountered in a few cases; but, apart from these, digestive disturbances are rarely observed.

In full grown animals placed on diets poor in vitamin A, xerophthalmia is not liable to develop as promptly as in younger rats, but it appears in a considerable number of instances if the deficient dietary is continued long enough.

The characteristic ophthalmia just described is not limited to the albino rat. It has been observed to occur in a variety of other species, including man, when there is a shortage of vitamin A in the rations. For some time, mice were supposed to be somewhat immune to xerophthalmia due to dietary deficiency, but this species also has recently been shown to succumb with characteristic symptoms of eye disorder to lack of vitamin A.

Particular interest has been centered latterly in the evidences of respiratory infections consequent on a dietary deficient in vitamin A. Thus, observers have reported "a nasal or bronchial catarrh or even pulmonary infection with mucous or purulent exudate, at times even resulting in hemorrhage. Animals thus afflicted in the early stages of the disease sneeze and cough violently but later, as the inflammation becomes confined more to the lungs, the cough subsides, and dyspnea becomes very pronounced with the slightest activity." In addition to this it is common, in rats at least, to find abscesses near the base of the tongue and in the pharynx, pus in the middle ear, and sometimes sinusitis. Sherman and Storms believe that when rats of the same stock and previous nutritional history are placed on the same vitamin A-free diet at different ages, the ophthalmia develops in a larger proportion of the younger, and respiratory disease in a larger proportion of the older, animals. Another experimental clinical feature early discovered by Osborne and Mendel is the large incidence of calculi and calcareous deposits at various regions in the renal passages and urinary bladder in rats long deprived of vitamin A. The cells of the renal tubules seem to become "calcified" in some instances. There is a high incidence of urolithiasis in rats deprived of vitamin A. These manifold disorders and distortions of structure make clearer why it often becomes difficult if not impossible to induce restoration of health by suitable changes in diet. The parts affected, like the ocular tissues or the kidneys, may have become so extensively deranged that repair is interfered with or the harm becomes irreparable. In children, blindness has often ensued.

## PATHOLOGY

The pathologic changes evident on microscopic examination in cases of A-avitaminosis have already been studied by several investigators. Wolbach and Howe concluded that the outstanding change is a substitution of stratified keratinizing epithelium for normal epithelium in various parts of the respiratory tract, alimentary tract, eyes and the para-ocular glands and the genito-urinary tract. The histologic change characterized by a transformation of cuboidal into keratinized cells seems to be due directly to the nutritional deficiency; infection then readily attacks the weakened tissues. According to Tyson and Smith the principal changes associated with vitamin A deficiency in rats are a metaplasia of cuboidal or columnar epithelium in certain parts of the body, epithelial hyperplasia in various structures, and infection. The metaplastic changes involve the following structures in order: the sublingual glands, the submaxillary glands, and the epithelium of the renal pelvis and of the trachea and bronchi. The tongue is regularly involved before xerophthalmia appears. The serous type of sublingual gland is the first to be affected. The lesion in the tongue and submaxillary gland begins with a dilatation of the ducts and a metaplasia of the lining epithelium accompanied by infection. In late cases the glandular tissue may be entirely destroyed by pressure from the dilated ducts and by necrosis due to infection. The submaxillary gland is not involved as constantly as the tongue. The epithelium of the renal pelvis may be involved quite early. Metaplasia and infection are always present in the advanced cases. Renal calculi are prone to occur, and when obstruction to the urinary outflow is present pyonephrosis develops, which is sometimes followed by perinephric abscess. Epithelial metaplasia of the trachea and bronchi is not common. The most usual condition is an atrophy of the lining cells.

Closely related to the epithelial changes just described is a characteristic test for deficiency in vitamin A described in 1922 by Evans and Bishop. This is the constant appearance of cornified cells either predominantly or exclusively in the vaginal smear. During the estrous cycle of the female rat it is easy to demonstrate a succession of recurring types of cells obtainable from the vaginal surfaces. During impoverishment of vitamin A, the cornified cells persist. According to some observers this manifestation is earlier and, since invariable, more constant in its appearance than xerophthalmia or abscesses of the glands at the base of the tongue and, while perhaps not earlier than growth decline, as pathognomonic of vitamin A deficiency as growth decline is not. An inadequate supply of vitamin A injures the female reproductive system so that fertilization and implantation often fail. In this respect it differs radically from the reproductive impairment due to low vitamin E content, in which, typically, the eggs are always healthy and implantation takes place but resorption follows. Lack of vitamin A leads to sterility in the male rat.

### VITAMIN A ASSAYS

The prevalent method of estimating the content of vitamin A in a food or preparation thereof is the curative biologic procedure already referred to. It is based on the principle of depleting young albino rats of their reserves of vitamin A by an otherwise suitable diet devoid of this factor and then determining the minimum amount of the product under examination that is required to produce a standard response. The details vary widely according to the preferences of the assayers. In the case of cod liver oil the U. S. Pharmacopeia X adopted the following routine:

> Vitamin A Assay for Cod Liver Oil.—Cod liver oil may be assayed by the following process. When so assayed the oil should contain at least 50 units per gram and must be labeled "This unit is not a measure of the antirachitic activity of cod liver oil."
>
> This assay is based upon the estimation of the minimum amount of cod liver oil necessary to meet specific growth-promoting requirements in a standard test animal. The test animals shall be albino rats from a constant source and bred preferably under the control of the experimenter.
>
> The vitamin A potency of cod liver oil shall be expressed in units per gram of oil, the unit to be the minimum daily amount of cod liver oil required to cure induced symptoms of vitamin A starvation in young albino rats, and to cause a gain in weight of from 10 to 20 Gm. within a period of thirty-five days under the conditions of growth and diet specified in this assay.
>
> Place on a vitamin A-free diet, rats not less than twenty-five days and not more than twenty-nine days old, and weighing not less than 35 Gm., and not more than 45 Gm.
>
> The basal diet is to be composed as follows: Casein, or desiccated fresh meat, rendered free from vitamin A, 18 per cent; salt mixture, such as that of Osborne and Mendel or McCollum and Davis, 4 per cent; starch, sufficient to make, 100 per cent.
>
> Use sufficient dried brewers' yeast to meet the vitamin B requirements of the animal, mixing it with the basal diet during the vitamin A-free period.
>
> The rats shall begin receiving the cod liver oil to be tested after not less than seven days of stationary or declining weight, and from the time of feeding the test oil, they shall be kept in separate cages.
>
> The test period shall continue for thirty-five days and the potency of the oil shall be judged from the rat or rats showing a gain on the thirty-fifth day of between 10 and 20 Gm. over the weight at the beginning of the test, and the cure of the induced symptoms of vitamin A starvation.
>
> Each test shall be controlled by at least two standard rats which have received no cod liver oil. These animals may serve as controls for any number of concurrent tests on which the same basal diet is used.
>
> No oil shall be labeled as assayed by the U. S. P. method unless it contains at least 50 units per gram of oil.
>
> The diet for rats used as breeders shall be composed as follows: Finely ground whole wheat, 66 per cent; whole milk powder, 33 per cent; sodium chloride, 1 per cent.
>
> The antirachitic requirements of the breeders shall be assured.

This "official procedure" has been the subject of widespread criticism for many reasons that need not be detailed here. At present a committee of experts has been organized to devise a revised assay outline for the next edition (XI) of the U. S. Pharmacopeia. Improvements in technic have been introduced into current food assay practice, notably by Sherman and his co-workers.[1] Attention has been given to the development of a basal diet that shall be free from vitamin A but fully adequate in all other respects and that can be duplicated with certainty. The basal vitamin A-free diet now used consists of purified casein 18, salt mixture 4, dried brewers' yeast 10, sodium chloride 1 and cornstarch 67 parts, with the addition of 0.5 Gm. of irradiated commercial cholesterol per kilogram of the basal ration or some equivalent form of irradiated ergosterol. A unit of vitamin A is defined by Sherman as

> that amount which when fed daily to a standard test animal, prepared as described, will suffice to support an average gain in body weight of 3 grams per week during the test period of 4 to 8 weeks. (Obviously one may always express vitamin A values in terms of this standard unit, and yet may state the number of such units contained in one gram, or one kilogram, one ounce, one pound, or in a 100-calory portion of the food, or in whatever other amount of food may be regarded as convenient—as for example, the number of units of vitamin A in a dozen eggs.)

It should be added that, unfortunately, considerable difference of opinion still exists among both American and European biochemists regarding the most suitable technic and the appropriate "unit" to be adopted. Although it has become possible to express the results of feeding tests in terms that are, broadly speaking, quantitative in character, there is not as yet sufficient uniformity of practice to satisfy the needs of a dependable standard that is internationally acceptable. Hence it is important in every instance to know something about the assay method that has been employed in the examination of a product quantitatively for vitamin A. An international vitamin A unit equivalent to $1\gamma$ (0.001 mg.) of pure carotene has recently been proposed.

For a time it appeared as though a strictly chemical method might become available. Liver oils that are rich in vitamin A, as determined by biologic methods, give striking color reactions under certain conditions. Often a parallelism between the intensity of the developed color and the richness in vitamin A seemed to exist. It was suggested, therefore, that the reactions might be due to vitamin A or to some related substance.

---

[1] Sherman, H. C., and Smith, S. L.: The Vitamins, ed. 2, New York, Chemical Catalog Company, Inc., 1931.

In the case of colored foods and natural products the fat-soluble vitamin is removed by means of organic solvents; interfering pigments can usually be separated by suitable adsorbents. When a solution of antimony trichloride in chloroform, for example, is added to cod liver oil, a blue color appears. The conditions of one procedure are as follows: Antimony trichloride washed with chloroform and dried is dissolved in chloroform to make a 30 per cent solution (weight in volume). After standing, the clear solution is decanted and used from a buret. The oil to be tested is dissolved in chloroform (20 per cent solution) and to 0.2 cc. delivered from a 1 cc. buret, 2 cc. of the antimony trichloride solution is added. The liquid is at once transferred to a cell and the blue color intensity measured against standard glasses in a Lovibond tintometer. The earlier literature on color tests for vitamin A is reviewed by Willimott and Wokes.[2] The lack of dependable correspondence between the chromogenic values for vitamin A-bearing fats and the biologic assays has thrown doubt on the value of the simpler methods. At the present time the value of the colorimetric methods—and there have been many suggestions—is *sub judice*. As a recent reviewer has pointed out, thus far the chemical reactions appear merely to be suggestive of the vitamin A content of some fatty compounds, particularly cod liver oil. They are not serviceable as sole indicators in quantitative determinations of vitamin A. As previously, such estimates have still to be made by means of animal experiments. For this, the rat is the most suitable animal.

### CHEMISTRY OF VITAMIN A

As might be expected, the chemical nature of vitamin A has from the outset been the subject of intense scientific curiosity. It would also be of immense practical importance if the potent substance could be isolated in pure form. Its solubilities were early found to correspond to that of fats, with which it seems to be associated quite often in nature. It can be extracted along with fats and lipoid substances from natural products by means of organic solvents like ether. Vitamin A is, however, not a fat, that is, an ester of a familiar fatty acid; for when vitamin-bearing fat mixtures like cod liver oil are saponified, vitamin A appears in the nonsaponifiable portion of the reaction mixture. It can thus be removed from fats by saponifying the latter. Manifold concentration can thereby be effected. This process is employed in the preparation of the vitamin A concentrates of cod liver oil that are available in commerce and employed as therapeutic agents.[3] Long ago, Drummond succeeded in effecting a thousandfold concentration of the vitamin A of cod liver oil, but he regarded the product as still grossly contaminated with adherent impurities. In criticizing earlier reports on the alleged isolation of the potent principle, Drummond expressed the belief in 1929 that "the active substance is present in liver oil concentrates in amounts so minute that direct attempts at its isolation by the ordinary chemical methods are of little use." He adds that

> the color reactions believed by many to be specific for vitamin A recall so strongly those given by certain types of sterol derivatives, that it is probable that more progress in elucidating the nature of the active substance will be made by studying the properties of sterols than by continuing to employ such methods as we have used during the last ten years. It is encouraging to recall the brilliant success which has followed the studies of the sterols in relation to Vitamin D, and to remember that the concentrated preparations of the antirachitic vitamin that are now available would probably never have been obtained by employing such methods as we have used in attempting the isolation of vitamin A.

Drummond reported that a sample of Japanese shark liver oil possessing a vitamin activity of the same order as a good cod liver oil yielded an unsaponifiable fraction of which from 90 to 95 per cent was accounted for in the form of reasonably pure preparations of alcohols, together with small amounts of cholesterol and a hydrocarbon resembling squalene. The remainder appeared to consist to a large extent of the same substances. This would indicate that the vitamin A forms a very small proportion of the unsaponifiable matter, probably less than 1 per cent. About 5 per cent of the oil consists of unsaponifiable matter. As less than 5 mg. of good liver oil suffices to supply the daily requirement of a 100 Gm. rat, it is readily calculated that the vitamin A in the daily intake represents at most a magnitude of approximately one part in a million parts of body weight. Such are the amazingly small concentrations of certain chemical substances that spell well being versus the nutritive failure that ensues without them. The story furnishes an added illustration of the large importance of "little things" in nutrition.

Vitamin A can readily be destroyed by oxygen or oxidizing agents at high temperatures. It appears, however, that in the forms of the chemical "environment" in which it exists in many of its natural sources the vitamin is somewhat more resistant to destruction than was formerly assumed. The reaction and the presence of antitoxidants may play a part in this protection. The attempts to regenerate vitamin A in products in which it has been destroyed have not been successful thus far. Vitamin A appears to be less resistant to destruction when it is separated from the products with which it is associated in nature. It possesses sufficient stability, as it exists in most of the common foods in which it is found, to undergo the modern processes of food conservation, notably food preservation by present-day commercial canning operations, without serious destruction. Recent studies of Kohmann and Eddy indicate that neither fruits nor vegetables lose appreciable amounts of vitamin A in the home cooking or canning process. The vitamin A assay of cod liver oil preserved in the absence of air remains quite constant over periods of many months.

### CAROTENE AND VITAMIN A

During the early progress in the study of the distribution of vitamin A in natural products, a possible relationship between this food factor and certain carotinoid pigments suggested itself. Some of the familiar foods, such as butter and carrots, that were rated as comparatively rich in vitamin A exhibit a pronounced yellow color. The comparison is notable in the case of maize, the yellow kernels being decidedly more effective than the white ones as sources of vitamin A. Comparable differences have been reported between the yellow and the white varieties of yautia. Many green food products carry carotinoid pigments masked by the green color. There appears to be a relationship between the green products and vitamin A potency. It has been clearly established, for example, by comparisons of bleached and of green asparagus and by the differences between pale head lettuce and green leaf lettuce. The parallelism though striking in many instances does not hold, however, for a considerable number of well tested substances. Cod liver oil, rich in vitamin A, is devoid of the yellow pigment; hence the assumption that fats [illegible] are richest in vitamin A cannot be [illegible]

---

[2] Willimott, S. G., and Wokes, Frank: Lancet 2:8 (July 2) 1927.

[3] Cod Liver Oil and Cod Liver Oil Preparations: New and Nonofficial Remedies, 1931, p. 259.

The pigments responsible for the comparative "yellowness" of the products referred to are carotene and xanthophyll. The latter has been excluded from any responsibility for vitamin A potency. The early tests with purified carotene gave negative results for the most part. Subsequently, however, von Euler in Sweden and Moore in England furnished striking evidence that very small doses of the highly purified yellow pigment carotene (sometimes spelled carotin) suffice to cure rats that exhibit the symptoms of avitaminosis due to lack of vitamin A. A daily intake of not more than 0.003 mg. of carotene has been found effective. This forms the basis for the proposed use of carotene as a standard for vitamin A assay, already referred to. The failure of earlier investigators has been explained by the destructive nature of the pigment solvents used in their tests; for carotene is very sensitive to oxidizing reagents and loses color readily when in contact with certain chemicals.

Vitamin A cannot well be regarded as identical with carotene. There are numerous indications that the classic material having biologic properties designated as vitamin A is a colorless substance. It has therefore been assumed, as might be expected, that carotene has been found potent because of contaminating traces of vitamin A in the products thus far tested. Such an assumption applied to highly purified—and highly potent—carotene would endow the minute amounts of contaminant thus postulated with almost unbelievable potency from a purely quantitative standpoint. Other objections also can be raised. They deal with the unlike spectrographic properties of the two substances.

The confusion and uncertainty regarding the possible relationships between vitamin A and carotene, and perhaps other organic compounds (dihydro-α-crocetin) have been dispelled latterly by the discovery that the pigment apparently can be converted into vitamin A in the animal body. When rats are deprived of vitamin A in their diet, the liver soon becomes depleted of the stored vitamin. Administration of carotene at this stage relieves the symptoms of avitaminosis and may bring about fresh storage of pigment-free vitamin A. It thus appears that carotene can function in the body as a precursor of vitamin A. The researches of Moore and others afford a complete picture of the conversion of carotene in vivo to the familiar vitamin A of liver oils, as defined by all the chromogenic and spectroscopic properties that have been found to run parallel to this factor. The details of the conversion are summarized in table 1. A new chapter in the story of the vitamins has been begun.

TABLE 1.—*Conversion of Carotene to Vitamin A*

| Carotene ⟶ | Vitamin A |
|---|---|
| Synthesis in plant | Stored in animal |
| Intensely yellow | Almost colorless |
| 328 millimicron absorption band absent | 328 millimicron absorption band developed |
| Greenish blue antimony trichloride reaction at 590 millimicrons | Vivid blue antimony trichloride reaction at 610-630 millimicrons |

### ORIGIN OF VITAMIN A

As in the case of the other recognized vitamins, the animal is dependent on exogenous sources for its requisite supply of the indispensable vitamin A. It cannot be synthesized de novo by the animal organism, but the latter can store considerable quantities in certain tissues. The content of vitamin A depends largely on the diet of the animal. Vitamins do not form any exception to other types of "essentials" for growth and physiologic well being, in that they must be supplied preformed or practically so to the individual. This is true of indispensable amino-acids, such as lysine, tryptophan and histidine, for instance. The essentials are synthesized by plants; and from them the animals of both land and water derive their supplies either directly or indirectly by preying on other animals. Bodansky has thus summarized his conclusions concerning vitamin A:

TABLE 2.—*Relative Distribution of Vitamin A in a Few Common Foods*

- Minimal or Unappreciable Amounts
  - Beets
  - Celery
  - Egg white
  - Flour (white)
  - Honey
  - Hydrogenated fats
  - Lard
  - Onions
  - Radishes
  - Rice
  - Starch
  - Sugar
- Fair Amounts
  - Apples
  - Beans (navy or soy)
  - Bread
  - Cabbage (cooked)
  - Cauliflower
  - Fish
  - Oatmeal
  - Parsnips
  - Potato (white)
  - Rye
  - Wheat (whole)
- Good Sources
  - Asparagus (green)
- Good Sources—Continued
  - Beans (green)
  - Bread (whole wheat, milk)
  - Cabbage (raw, green)
  - Carrots (cooked)
  - Cheese
  - Corn (yellow)
  - Dandelion greens
  - Lettuce
  - Liver (beef)
  - Milk (human)
  - Orange juice
  - Oysters
  - Peaches
  - Peas
  - Potato (sweet)
  - Pumpkin
  - Tomato
- Excellent Sources
  - Butter (high grade)
  - Carrots (raw)
  - Cod liver oil
  - Cream
  - Eggs
  - Milk (cow's, fresh, dried, evaporated)
  - Spinach
  - Watercress

> There is no reason to doubt that the green plants of the water as well as those of the land synthesize this vitamin under the influence of sunlight. Many of these diatoms, minute algae, and other tiny aquatic plants become food for the group of small sea organisms known as plankton and this in turn for larger species up to the crustaceans and small fishes on which codfish feed. In such ways the synthesis of vitamin A in the small green plants of the sea presumably becomes the source of the abundant supplies of this substance which we find in cod liver oil; the cod, it will be remembered, having very little fat elsewhere in its body.

### FUNCTION OF VITAMIN A

Existing knowledge permits little more than vague speculation respecting the mode of action of vitamin A. The description of the dire consequences of a deprivation of this food essential gives little insight into precisely how it functions in the tissues. One may ask whether it is a necessary integral part of structures like the epithelial cells or whether it acts as a catalyst or as a "regulator" of certain cellular functions. There is some debate as to whether vitamin A can properly be designated as an anti-infective vitamin, as has been done. It is quite likely that its influence is felt indirectly in that the vitamin helps to preserve the physiologic integrity of various epithelial structures and thus to maintain the "first line of defense" against the invasion of bacteria. Evidence for direct bactericidal action or for a relation to the development of "immune substance" has not been easy to secure. For the present it may be wiser to stress the indefinite function of the vitamin in preserving "health and vigor" rather than to herald any specific action against definite microbiotic enemies. Deficiencies of any sort tend to decrease the ability of the body to resist disease.

There is no reason to assume that "digestion" is a requisite for the absorption and utilization of vitamin A. It has the solubilities of fats and usually accompanies them. Fats normally require bile for their absorption. Using the vaginal smear picture as a criterion, Schmidt has demonstrated, however, that vitamin A can be absorbed from the gastro-enteric tract even when bile is excluded therefrom. It has been shown, furthermore, that vitamin A can be utilized when it is administered parenterally; that is, without introduction by way of the alimentary canal. Carotene likewise functions effectively when injected parenterally in A-avitaminosis. These facts have paved the way for the parenteral therapeutic use of vitamin A-bearing products in cases in which a defect or disease of the alimentary tract has interfered with the oral administration of the essentials.

### DISTRIBUTION OF VITAMIN A

Our knowledge of the distribution and content of vitamin A in food products and in certain medicinal products has been greatly increased of late. Each month brings new details. Space does not permit the presentation here of a catalogue of vitamin A in foods. A few common articles of diet are listed in table 2, classified according to their relative richness in vitamin A. The data represent no more than crude approximations. As has already been intimated, much depends on the mode of preparation (heat, oxidation), the state or stage of maturity in plant foods, and other factors subject to local or individual variation.

H. A. CARTER, Secretary.

# MEDICAL DIATHERMY

JOHN S. COULTER, M.D.
CHICAGO

Medical diathermy is the production of heat for therapeutic purposes in the body tissues, insufficient in amount, however, to produce temperatures high enough to destroy the tissues or impair their vitality. The heat is produced by the passage of alternating currents of high frequency through the tissues between two electrodes. The therapeutic effects are limited to the heat produced. The physics of these currents has been considered in another article. Only the clinical uses of local medical diathermy will be considered in this article.

The use of diathermy in pneumonia caused Binger and Christie[1] to undertake a number of experimental investigations on dogs to determine the action and physiologic effects of medical diathermy. These investigations showed that the efficiency or nonefficiency of the local circulation determines whether the heat produced by the passage of high frequency currents through the living body remains localized or is disseminated throughout the body. The prevention of access of air to one lung, while its circulation was intact, resulted in little if any change in the rate of heating of the lung by the diathermy current.[2] Occlusion of a main branch of the pulmonary artery during the flow of the current resulted in a sudden rise in temperature in the lung to which the artery had been occluded, with subsequent heating, however, at the original rate. Death of the animal is accompanied by a precipitous rise in the temperature of both lungs. When the pulmonary veins as well as the artery to one lung are ligated, the circulation through the bronchial vessels also is stopped. Diathermy then results in a local rise in temperature in the lung, equivalent to that seen in the other lung after death.

The temperature of the right heart blood normally exceeds that of the left heart blood by from 0.05 to 0.2 C. degree.[3] During the application of high frequency currents to the thorax, this relationship is reversed. This indicates that the lungs are being heated but that the blood passing through the pulmonary vessels is removing the heat at approximately the rate of production.

From experiments[4] performed on anesthetized dogs, the following conclusions may be derived: 1. The heat gradient of the body is reversed during diathermy, and heating occurs from without inward. 2. Deep heating during diathermy is greater than that which results from the application of local heat to the skin. 3. The lung can be heated by diathermy in spite of simultaneous cooling of the chest wall. 4. These experiments were regarded as satisfactory evidence of the passage of the current through the interior of the body.

In an experimental pneumonia[5] with more or less lobar distribution produced in dogs, measurements of lung temperature made by means of thermocouples before and during diathermy show that the final excess in temperature in the pathologic lobes over the normal lobes amounted to slightly more than 1 degree C.

Binger and Christie,[6] in another series of experiments, found that the behavior in human cases of pneumonia in respect to local heating of the lung during diathermy differed from that of the experimental animals. In the three patients studied by them there was no appreciable rise in lung temperature as compared with the rectal temperature. This difference is possibly due to the fact that the animals were under an anesthetic; their heat regulating mechanism was paralyzed, and therefore a far greater rise in systemic temperature occurred in them than in the patients. Secondly, the human lung is considerably larger than that of the dog, and the chances are correspondingly less of lodging the thermocouple in an ischemic area. Thirdly, for obvious reasons it was impossible to use as great a current in patients as in dogs. These authors state that this negative evidence does not necessarily imply that it will be impossible to demonstrate the occurrence of a slight degree of local heating.

The authors, in considering the disappearance of cyanosis so commonly recorded by those who use diathermy in pneumonia, examined the arterial blood for its oxygen content and capacity and found no significant changes. They therefore conclude that, if there is no increase in the percentage of the oxygen content of the arterial blood, the improvement in the patient's color must be explained on the grounds of a peripheral capillary effect—perhaps an accelerated rate of blood flow through the skin.

[6] Binger, C. A. L., and Christie, R. V.: Diathermy in Pneumonia, J. A. M. A. **91**: 367 (Aug. 11) 1928.

Diathermy does appear to have some value in the treatment of pneumonia. There is one fairly constant response to diathermy and that is the relief of pain.[7] The degree and duration of this relief vary in different patients.

Diathermy cannot be considered a specific cure for pneumonia.[8] It has proved a helpful therapeutic adjunct. It has not been proved that the duration of the disease has been affected by the use of diathermy, but symptomatically the results have been good. Its exact action is still unknown and further investigation is urgently needed.

Diathermy has been used in essential hypertension and has been recommended for a number of years, but, as is so often the case, the subjective improvement is without any appreciable change in the blood pressure,[9] at least for any extended period of time.

Diathermy has been advocated by some as having value in improving the circulation in peripheral vascular occlusions.[10] It may be used locally or to induce an artificial increase of temperature. Great care should be exercised to avoid burns. It should be used as an adjunct to other forms of treatment and usually combined with circulatory exercises, continuous heat with an electric baker and hot and cold alternate baths. Early cases of circulatory impairment may be definitely benefited and the progress of the disease may be arrested. It is clear, however, that in a complete vascular occlusion, with adequate collateral circulation, such measures can only fail and do no good.[11]

In diabetic gangrene, the essential feature is an insufficient arterial supply, and therefore the application of diathermy in the treatment of this condition is logical. In 1924, Chevalier and Chezet of France reported results. Barbash[12] reported a series of cases of successful treatment of gangrene of the diabetic type by medical diathermy. He believed that the effect of diathermy on the collateral circulation was lasting and appeared to be permanent and sufficient to maintain a good blood supply to the affected parts. De Takáts[13] uses medical diathermy as a test for this condition. When a diathermy current of from 1,000 to 1,500 milliamperes was applied to the lumbosacral region for thirty minutes with one large electrode in front and another in the back, individuals with normal peripheral circulation showed a marked rise in surface temperature. Patients with organic vascular obstruction show no alternation of temperature or just a perceptible rise. Patients with obstruction and some spasm show some change, but the temperature does not rise to the normal level of vasodilatation.

Hyperthermia by means of diathermy can be used for the treatment of these conditions. The effect of local heat in arterial spastic disease is not as lasting in relieving the pain and spasm as the application of heat to raise body temperature. Scott and Morton[14] produced this hyperthermia by two methods: diathermy and hot baths. In all cases both procedures caused a relaxation from arterial spasm which outlasted the hyperthermia produced, and pain was temporarily alleviated. They have not yet followed these patients long enough to determine how effective these measures will prove in permanently keeping the spasm under control. They believe, however, that diathermy and hot baths produce a much more desirable form of hyperthermia than that following the injection of foreign protein.

The use of diathermy in acute gonorrhea has been discounted by recent textbooks of urology. If one remembers that the gonococcus in culture will survive thirty minutes at a temperature of 113 F., little promise of cure by the heating of the gonococci in the tissues will be expected.[15] Jeck[16] says that the results of diathermy in the complications of gonorrhea in patients at the Bellevue Hospital have been disappointing.

In acute epididymitis the elevation of temperature by diathermy is distinctly beneficial for the relief of pain and the hastening of the subsidence of the infection. It has been questioned whether it should be used, because the great heat may destroy temporarily or permanently the spermatogenic function of the testicle; but it is doubtful that degree of heat is significant, especially when the disease itself destroys spermatogenic function.

In benign enlargement of the prostate in a series of cases[17] it was believed that local diathermy with a rectal electrode did not produce more benefit than the usual routine treatments.

Kelly[18] says that medical diathermy is used in salpingitis as an adjunct to the usual methods of treatment. The customary medical procedures are carried out with the addition of the use of diathermy with the electrodes, 6 by 6 inches, one on the suprapublic area and one over the sacrum. The first treatment is given for forty minutes with a maximum of 750 milliamperes. Any increase in pelvic pain or immediate elevation of more than 1 degree in temperature contraindicates diathermy for a time. Gellhorn[19] advocates the use of diathermy in pelvic infections by the use of a belt electrode encircling the waist of the patient and a vaginal electrode which surrounds the cervix, or a rectal electrode, giving a treatment of from twenty to thirty minutes daily. In pelvic inflammatory diseases the good that diathermy accomplishes is in all probability due to the increase in circulation brought about by the local application of heat rather than from any heat generated in the tissues themselves, and surely not from any destruction of bacteria by heat.[20] It is best employed in women experiencing their first attack, in whom the acute symptoms and fever have subsided. It is of much less value in recurrent cases. Its use is contraindicated in the presence of complicating pelvic conditions such as myoma uteri and ovarian cysts or tumors; neither should it be employed during menstruation or in the presence of profuse bleeding of inflammatory origin. The use of diathermy in pelvic infections is not accepted as a method of procedure by many gynecologists. The whole subject needs further research along the lines investigated by Royston and his associates.[21] With the Zener cervicovaginal electrode these authors were able to secure temperatures averaging 111 F. in the cervical canal and 108 in the urethra and the rectum, but it was impossible to maintain such degrees of heat for a period of more than five to eight minutes owing to the dissipation of heat by the blood stream. In their series of cases, all patients were symptomatically improved. When temperatures above 113 were used, the patient invariably complained of an increase in pelvic pain and tenderness following treatment. It would therefore seem unwise to employ this treatment unless it is possible to check carefully the temperature produced.

In considering the reported results[22] of diathermy in calcified subdeltoid bursitis, it is wise to remember that in some cases these deposits disappear without any treatment whatever. If the deposit of a calcium salt reacts like any other calcium deposit, in that it may form without an apparent cause, it is often fragmented and may disappear spontaneously as well as under the influence of such treatment as diathermy. In the sharply localized and tender deposits, Osgood believes that it is simpler and quicker to remove the calcified deposit by a small incision and a curet.[*]

Treatment of bursitis by means of diathermy has many advocates. Deering[23] asserts that in 1916 he made the first recorded attempt to treat subdeltoid bursitis "by means other than drugs, surgery or orthopedic measures" and states that there is rarely if ever a case in which deposits are present that cannot be made to recover by conservative measures in which diathermy plays a large part. Cooperman,[24] Harris,[25] Resnik[26] and Titus[27] believe that the deposit can be dissipated under the influence of diathermy. In sixteen cases reported by Mumford and Martin,[28] the electrodes used were of block tin, which is pliable and can be made to conform to the contour of the part. A treatment of from thirty to forty minutes was given. In this series of sixteen patients with bursitis, all secured complete relief from symptoms. The average number of treatments was twenty-one, given daily for the first two weeks and then twice a week.

In experimental work on the influence of local diathermy on kidney secretion, in three animals that tolerated 600, 825 and 900 milliamperes, respectively, the results obtained were consistently negative in sixteen diathermy and twenty-four control experiments on the first dog, eight diathermy and eight control experiments on the second dog, and twelve diathermy and twelve control experiments on the third dog, and Friedman[29] was unable to demonstrate any effect of diathermy on the rate of the secretion of urine. His results on the rate of the secretion of urine are quite in accord with those obtained by Bronner and Schüller[30] on the normal human being, but not with those of Ewig, which will be noted later.

Results opposite to the foregoing were observed by several European observers who recommend diathermy in the treatment of nephritis. Eppinger[31] recommends diathermy for the treatment of acute nephritis. Ewig[32] reports the influence of diathermy on the healthy and the diseased kidney. He found that diathermy of the healthy kidney causes increased diuresis. Not only the elimination of water is increased, but to a lesser degree also that of sodium chloride and of the nitrogen-containing substances. Kolischer and Jones[33] have also recommended diathermy for the benefits resulting from the heat produced within the perirenal and the renal structures by the resistance which these parts offer to the high frequency current forced through them. They state that the efficiency of any antinephritic treatment depends to a great extent on its early administration, and the same holds good for diathermy. Medical diathermy is by no means a cure-all or a specific for nephritis. It is simply an aid and will furnish results only in combination with the other therapeutic measures indicated, such as removal of the etiologic infectious foci, the proper dietary regimen, adequate cardiac treatment, the administration of diuretics and, if suggested by the prevailing conditions, nephrolysis and decapsulation.

Diathermy has been recommended[34] as a valuable means of controlling pain, spasm and swelling in the earlier stages of fractures and joint injuries. These results were not borne out in a series of experiments by Benson[35] to determine the relative influence of diathermy and other physical therapeutic measures on stiffened joints. On trying to restore normal motility in joints after "athletic injuries," he found that hot air is the most efficient medium; whirlpool treatments are somewhat less efficient than hot air, but if not preceded by other heat treatments, diathermy gives only a slight increase in motility. When used after other forms of heat, it produces a distinct decrease in motility. In either case, movements are apt to be more painful for some time after diathermy than before. He attributes the negative influence of diathermy to muscular rigidity induced by the high frequency current. Whether or not such rigidity is muscular or neuromuscular in character, direct or reflex, it is impossible to state. The rigidity tends to increase with the intensity of current applied and with the duration of treatment. Whenever the aim is to relax tissues or reduce stiffness of joints, the most effective method is hot air; the most rapid is hot water or the whirlpool bath. Diathermy, if applied, should be used alone or should be followed by the whirlpool bath or by applica-

tions of hot air. In either case it should be applied briefly and with a current of small intensity.

In arthritis, diathermy is contraindicated in the active joint and has proved disappointing in many chronic cases.[36] At times medical diathermy in arthritis causes an aggravation of the local symptoms.[37]

The effectiveness of diathermy in the treatment of deafness has not yet been proved. Guttman and Kulvin[38] subjected to treatment with diathermy forty-two persons who complained of being hard of hearing. In nine cases of otosclerosis, two cases of tubal occlusion and one case of serous otitis, benefit was not observed, as indicated by carefully controlled voice and audiometric tests. Only three of thirty-two patients with chronic otitis media were improved; whether the improvement reported was actually due to the treatment is open to question. This form of therapy was also ineffectual against tinnitus in otosclerosis. Thirty-three of the forty-two patients believed that they were benefited by the treatment and thought they could hear better. Yet actual tests showed that this was true in only three instances. The improvement therefore was only apparent. This method of treatment makes a decided impression on the patient's mind and any benefit must be of psychic or suggestive nature.

McKenzie[39] has used diathermy in deafness with fairly satisfactory results. By this method two electrodes, 1 by 1½ inches (2.5 by 3.7 cm.), thickly padded with lint soaked in 10 per cent salt solution are used. One is placed over the mastoid and the other over the cheek on the other side. Sessions of thirty minutes are given, and these are repeated every day or every second day at least six times. If there is no improvement, they are discontinued; if there is improvement, they are stopped for some weeks and then repeated. There is often an increase in the tinnitus at first, but this ceases later. McKenzie treated forty-six patients, most of whom had chronic dry catarrh. In five patients the deafness and tinnitus disappeared entirely after from two to six treatments. There was great improvement in five cases. The greatest improvement was obtained in cases of short duration. Of the remaining thirty-six cases, thirteen showed temporary improvement, twenty-one no improvement, and in two the tinnitus was made worse. Altogether, the condition was improved in 20 per cent of the cases.

The indications for medical diathermy in diseases of the eye are by no means well established, according to Gifford.[40] Medical diathermy may relieve pain in the neuralgia of herpes zoster. Monbrun and Casteran[41] report good results in certain corneal ulcers, especially those following facial paralysis. These authors advise against the employment of medical diathermy in intraocular diseases and consider it especially contraindicated in glaucoma.

Medical diathermy is now being extensively used to produce general hyperpyrexia. Neymann and Osborne[42] report a series of twenty-five patients with dementia paralytica treated by this method with clinical remissions in 66 per cent, marked improvement in 8 per cent, and no serious harm resulting to any patient from this treatment. In a comparative study of therapeutic results obtained in a series of clinically similar cases of dementia paralytica treated by this method compared with treatment by malaria and sodoku, the remission and improvement rate of the diathermy cases exceeded that of the other two.[43] Diathermy has also been used in the treatment of arthritis[44] and allergic disease.[45] These studies need extension and confirmation.

The following are some of the special safety rules given by Kovacs[37] for medical diathermy:

> Before applying electrodes inspect carefully the parts to be treated to make sure that the continuity of the skin is nowhere broken and that the heat sensation of the patient is normal. In case of scar tissue, peripheral nerve injuries, hysterical anesthesia, be extremely careful in the application of diathermy.
>
> Before turning on the current from the main inlet inform the patient that all the sensation he or she can expect is that of mild heat. Instruct the patient to report any uncomfortable faradic sensation, *pricking or burning, at once.*
>
> Do not try to push the current up to the maximum amount of toleration during the first few treatments. Patients often are burned in their endeavor to show how much current they can stand. Remember the principle that a moderate amount of heat applied for a longer period is more effective than pushing up to the limit of tolerance for a shorter period.
>
> If at any time during the treatment the patient complains of an uncomfortable sensation anywhere, turn off the controls, shutting off the main current inlet in case of emergency and, if necessary, take off, inspect and reapply the electrodes. When inspecting or adjusting electrodes, be sure that the current is turned off and increased gradually again after such a procedure.
>
> Do not leave the patient alone during treatment unless you have arranged that by the simple pulling of a cord or the turning of a switch the patient himself can turn off the current at any time. Watch the milliampere meter during the entire treatment for an even flow of the current.

Medical diathermy is contraindicated (1) in acute inflammatory processes such as acute nondraining cellulitis, acute infectious arthritis, and acute pelvic infection; (2) in any condition in which there is a tendency to hemorrhage, such as a gastric ulcer,[37] and (3) in those areas in which the appreciation of heat has been impaired or lost, as in certain peripheral nerve injuries. It is also contraindicated in diseases or injuries in which simpler methods of applying external heat give satisfactory results.

## CONCLUSIONS

This brief survey of some of the applications of medical diathermy shows the divergent views of its use. It is recognized that further laboratory and clinical research will doubtless establish many other therapeutic applications of diathermy. Of necessity, this article has dealt only with the present available evidence of the clinical application of medical diathermy. The urgent necessity for further research on the clinical use of this agent is obvious. It is possible to produce deeper heat with this agent than with any other form of heat. The circulation of the blood prevents the temperature of the body tissues traversed by the current from becoming very high. However, the active hyperemia resulting from medical diathermy causes beneficial physiologic effects, concerning which further scientific investigation is needed. Some recent uses in vascular disturbances of the extremities and in the production of artificial fever promise valuable therapeutic results.

# *Committee on Foods*

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

## COCOMALT

### (Sucrose, Skim Milk, Cocoa, Malt Extract, Egg and Added Vitamin D)

*Manufacturer.*—R. B. Davis Company, Hoboken, N. J.

*Description.*—A powdered food for the preparation of table beverages; contains sucrose, skim milk, cocoa, malt extract, whole egg, vanillin flavoring and added vitamin D (irradiated ergosterol).

*Manufacture.*—Cocoa (including added irradiated ergosterol), sucrose, and skim milk and egg powders are thoroughly mixed with malt syrup and vanillin flavoring. The mixture is dried at a relatively low temperature to avoid destruction of the vitamin and diastatic values. The finished product is ground, bolted and automatically packed in an atmosphere of carbon dioxide in hermetically sealed containers. The carbon dioxide composes about 75 per cent of the gas mixture in the container.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 0.8 |
| Ash | 3.2 |
| Fat (ether extract) | 2.9 |
| Protein (noncaffeine and nontheobromine N × 6.25) | 14.1 |
| Caffeine | 0.09 |
| Theobromine | 0.21 |
| Crude fiber | 1.4 |
| Carbohydrates other than crude fiber (by difference) | 77.0 |
| Calcium (Ca) | 0.34 |
| Phosphorus (P) | 0.43 |
| Lintner value | 6.3 |

*Calories.*—3.9 per gram; 111 per ounce.

*Vitamins.*—Vitamin D is incorporated in Cocomalt (under license by the Wisconsin Alumni Research Foundation) to the extent of approximately 39 Steenbock units per ounce. Biologic assay shows the presence of from 40 to 45 Steenbock D units per ounce.

*Claims of Manufacturer.*—Especially intended for the preparation of table beverages with milk. Cocomalt enhances the food value and flavor of milk. Many who dislike plain milk, especially children, invalids, convalescents and the aged, enjoy Cocomalt-milk beverage. One ounce of Cocomalt, which is recommended for each glass of beverage, contains from 40 to 45 vitamin D units (Steenbock) and richly contributes to the vitamin D dietary needs of the body. A hot beverage promotes relaxation. "A hot Cocomalt" before retiring is an aid to restful sleep.

## CHILOCCO BRAND CORN SYRUP WITH CANE FLAVOR

*Packer.*—D. B. Scully Syrup Company, Chicago.

*Distributor.*—Frank C. Schilling Company, Green Bay, Wis.

*Description.*—A table syrup; a corn syrup base (85 per cent) with refiners' syrup (15 per cent).

*Manufacture, Analysis, Calories, Claims of Manufacturer.*—See these sections for Banner Blue Corn Syrup with Cane Flavor (The Journal, March 5, 1932, p. 817).

## PORTOLA SARDINES (PILCHARDS).

### Steam Grilled—In Tomato Sauce and Olive Oil
### Steam Grilled—In Curry Sauce and Olive Oil

*Manufacturer.*—K. Hovden Company, Monterey, Calif.

*Description.*—Canned steam grilled sardines (Clupea caerulius, blue sardines) with tomato sauce, salt and olive oil or curry sauce, salt and olive oil.

*Manufacture.*—Pilchard Sardines (Clupea caerulius, or blue sardines) adult type, over 4 years old and of mature size are caught in the open sea off the coast of California during definite seasons four months after and three months before spawning. The sardines are delivered fresh each day. The catch is not iced in that the period before packing is very short, sometimes only a few hours. The fish are sluiced through water and kept in cold salt water to prevent bruising during handling.

The fish are pumped or hoisted from the boats into receiving tanks. Clean salt water is pumped over the fish and kept circulating during the short period of storage (two hours). They are sluiced into small boxes, in which the heads and tails are cut off and the entrails extracted by machine. They are conveyed by water into rinsing tanks, where scales, blood and excess slime are washed off with salt water. When the wash water becomes clear, the fish are conveyed on belts to the packers, who pack them into cans. The fish in cans are passed through cooking apparatus on grills. The grill travels with the cans spread right side up for eight minutes. The cans are automatically turned over on the belt so that the contents rest on the iron perforated grill, permitting the moisture, blood or other materials cooked out of the fish to escape and fall into a trap below. This process is repeated four times during the cooking. The fish in this process become solid and firm, take on an excellent flavor and do not come in contact with air. The fish are discharged on a belt conveyor. Tomato sauce, salt and olive oil, or curry sauce, salt and olive oil are added to each can. The cans are sealed while hot, which procedure produces a low pressure or "vacuum" after sealing. The sealed cans are placed in baskets and processed under the control of the California State Board of Health as to temperature and time.

*Analysis* (submitted by manufacturer).—

| (analysis of entire can) | per cent |
|---|---|
| Moisture | 60.4 |
| Ash | 2.8 |
| Chlorides as sodium chloride | 1.3 |
| Fat (ether extract) | 18.4 |
| Protein (N × 6.25) | 17.5 |
| Crude fiber | 0.1 |
| Glycogen | 0.2 |
| Carbohydrates other than crude fiber and glycogen (by difference) | 0.6 |
| Iodine (I) | 0.0006 |

*Calories.*—2.4 per gram; 68 per ounce.

*Claims of Manufacturer.*—These California steam grilled sardines are for all table uses. A dietary source of iodine.

## MARY JANE BREAD

*Manufacturer.*—Lowenberg Bakery, Ottumwa, Iowa.

*Description.*—A white bread made by the sponge dough method.

*Manufacture.*—The sponge dough ingredients, short patent flours of northwest and southwest wheats, water, yeast, malt syrup, and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose or dextrose, shortening and dry skim milk to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms for the materials used are kept in strictly sanitary condition.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 34.7 |
| Ash | 0.9 |
| Fat (ether extraction method) | 0.8 |
| Protein (N × 6.25) | 8.8 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 54.5 |

*Calories.*—2.6 per gram; 74 per ounce.

*Claims of Manufacturer.*—A bread of good quality.

## NUTRITION AND MILK PRODUCTION

Reproduction in the mammal presents special problems in nutrition. Not only must the requirements of the maternal organism be met, but the development of the fetus makes added demands on the supply of those substances from which the new tissue is formed. Whereas, at 28 weeks, the fetal content of calcium is approximately 5.4 Gm., at 40 weeks it has increased to almost 31 Gm. In spite of this storage of material, studies on various experimental animals and on man indicate that a positive balance of calcium, phosphorus and nitrogen is likely to be found during pregnancy. In other words, the usually observed augmented intake of food provides for the added demand of the fetus. After parturition, however, when vigorous flow of milk sets in, a considerable loss of certain essential materials in the milk occurs. This applies especially to calcium and phosphorus. The magnitude of this loss through the mammary glands and the extent to which it is covered by the food intake is of practical significance.

In a recent investigation, Macy and her co-workers[1] considered this general theme, paying particular attention to the energy, fat, protein, carbohydrate, calcium and phosphorus. Three human subjects were studied; the diets were not unusual but were adequate in quantity and, apparently, in quality. The breast milk was expressed at four-hour intervals and the average volumes were 3,134, 2,366 and 1,419 cc. With a daily energy intake of 4,300, 4,600 and 3,800 calories, it was observed that there was contained in the milk secreted energy equivalent to 50, 33 and 30 per cent of that taken in as food. Despite this relatively large proportion of ingested energy appearing in the milk, it is pointed out that together with the loss in excreta and the requirement for maintenance under the conditions imposed, it is covered by the calories of the food. The relations of the fat of the diet to that secreted in the milk for the three subjects were 74, 50 and 43 per cent, respectively; for the carbohydrate 47, 28 and 24 per cent, and for the protein 21, 15 and 12 per cent. The relatively low value for protein together with the known ability of the organism to transform protein to carbohydrate and the latter to fat leads to the conclusion that the production of the main organic constituents of milk does not ordinarily present a problem.

The situation as concerns the inorganic components, however, is different. The subjects consumed diets containing liberal amounts of calcium and phosphorus; 41, 27 and 15 per cent, respectively, of the calcium and 11, 11 and 6 per cent of the phosphorus of the food appeared in the milk. Although, according to current standards, the ingested calcium and phosphorus exceeded that required for the milk by a liberal margin, there was a persistent negative balance of these two elements. The subjects of this investigation "were unable adequately to absorb or utilize calcium and phosphorus while maintaining a high level of milk flow." Furthermore, other studies have emphasized the difficulty of improving the retention of these essential inorganic elements during lactation by such devices as are known to be effective under other circumstances.

These observations give cogent evidence for the considerable portion of ingested nutrients commonly lost to the maternal organism by way of the milk. In general, the food, when reasonably augmented, provides fairly adequately for this added requirement for lactation. However, improvement is needed in those processes involved in absorption and retention of certain of the food materials if the end result of the complete reproductive cycle is not to represent a loss to the body.

## THE TREATMENT OF STRYCHNINE POISONING

Strychnine poisoning is rather frequent, and its occurrence is rendered dramatic by the dreadful agony of its course and the commonly fatal termination. Most of the sources of poisoning could be easily avoided especially in the tragic cases of infants. Moreover, the agony of the developed poisoning can be completely eliminated and nearly all fatalities could probably be prevented by proper treatment.

Strychnine poisoning is sometimes suicidal or homicidal; occasionally it occurs from eating poisoned vermin bait;[1] but the most prolific source of strychnine poisoning is chocolate or sugar coated household laxative or "tonic" pills, which are left carelessly around the home and which look so much like candy that young children swallow them by the handful. The sweet and alcoholic "tonic" elixirs may also be a source of danger. The frequency of accidental strychnine poisoning has been reviewed by Aikman.[2] In the death registration area of the United States, in the three years 1926-1928, strychnine was reported as a cause of 546 deaths, or more than 3 a week. In the same period, the statistical bureau of the Metropolitan Life Insurance Company[3] reports that strychnine was responsible for about a third of the accidental poison deaths in children under 5 years of age insured in the company. This dreadful slaughter is the more regrettable since it has not been proved that the strychnine in these pills serves any useful purpose whatever in most patients. Generally the strychnine is merely a concession to the polypharmacal shotgun era. It has been retained on the easy-going assumption that, if it did no good, it could do no harm —to those who take the pills according to directions. Unfortunately, this is a good deal to expect of a child who cannot read and who takes the pills because they look like candy. Some restriction of the promiscuous sale of this violent poison in the guise of supposedly harmless household remedies is necessary. The trustees of the American Medical Association are considering the advisability of urging action along this line on pharmaceutic manufacturers.

[1] Hesse, E.: Sammlung von Vergiftungsfällen, 1, B. 2. 9, 1930.

[2] Aikman, John: Strychnine Poisoning in Children, J. A. M. A. 95: 1661 (Nov. 29) 1930.

The treatment of strychnine poisoning includes chemical antidotes, evacuation of the stomach, and sedatives. Since the strychnine spasms are provoked by anything that would startle a normal person, all sudden stimuli, however slight, must be strictly avoided. Gradual, steady movements for which the patient is prepared are harmless, and gently soothing handling and reassurance of the patient are fairly effective in mitigating even the established spasms, if these are not too violent.

Chemical antidotes are useful only against the unabsorbed poison, and chiefly against that which has not yet passed the pylorus. Either potassium permanganate solution or animal charcoal is quite effective in animal experiments. The charcoal does not destroy the poison but slows its absorption so much that it can be effectively destroyed in the tissues. Diluted iodine tincture or solution, and tannin, are useful chiefly as temporary measures preceding evacuation. Gastric lavage may be used early, before the patient has become hypersensitive, or later, when the sedatives have taken effect. If the patient is hypersensitive, evacuation should be secured by apomorphine, hypodermically (⅕ grain, or 0.013 Gm., for adults, ⅒ grain, or 0.006 Gm., for infants), since this tends actually to quiet and prevent convulsions.[4]

If the patient already has spasms or is even hypersensitive, sedatives should be administered freely. They ease the anxiety of the patient and suppress the painful spasms, and if they are used with intelligence and courage they diminish the fatality to a greater degree than is commonly realized, chiefly by preventing asphyxia from tetanization of the respiratory muscles. All sedatives are good, but some are much better than others. Quick action is imperative, and gastric administration is therefore undesirable, especially if the stomach has been upset by antidotes or lavage. Inhalation of chloroform is quite effective and may be used temporarily for immediate relief, although it is somewhat dangerous in view of the strain on the heart and the difficulty of controlling the vapor concentration during spasms. It should not be prolonged for fear of postanesthetic toxicosis. Ether inhalation is safer but less effective, and it is also inadvisable to prolong its administration. Nitrous oxide should not be used, since it exaggerates the reflex excitability and the asphyxia. Chloral hydrate, by rectum if necessary, was formerly esteemed as one of the most effective sedative antidotes, but the large doses required came to be considered unsafe. Other earlier aliphatic hypnotics also were unsatisfactory, since their action after oral administration was too slow and the effective dose, in many instances, too dangerous.

The barbituric acid derivatives have now opened a new chapter in the treatment of strychnine poisoning. They do not differ from the older hypnotics in principle but rather in the combination of high efficiency with relatively high safety, and especially by the fact that they may be administered intravenously in emergencies and therefore secure an effect that is immediate and the duration of which may be timed by the dose, by the repetition of the injections, and by the selection of the barbiturate. In such emergencies, intravenous injections are justified, not only by the need of immediate relief but also because the immediate effect permits the adjustment of the dosage to the desired response.

The anticonvulsant efficiency of the barbiturates first came into prominence in connection with cocaine poisoning.[5] In 1929, Soma Weiss[6] reviewed the successful use of subcutaneous, intramuscular and intravenous injections of sodium phenobarbital against the convulsions of eclampsia, epilepsy, procaine and traumatic tetanus. Zerfas and McCallum,[7] summarizing their experience with intravenous injections of sodium amytal, state that "it is practically specific for the treatment of strychnine poisoning. . . . Experimental animal work has shown that rabbits may be protected against several times the fatal dose of strychnine sulphate." No data are given. These authors also mention three clinical cases, all successful:

> A patient entered the hospital, in a series of continuous convulsions, after having swallowed two hundred one-thirtieth grain tablets of strychnine sulphate. He was cyanotic and was having great difficulty in breathing; 0.8 Gm. (12 grains) of sodium isoamylethyl barbiturate, given intravenously, checked the convulsions almost instantly, and the following day he was released from the hospital. Two other patients in a similar condition owe their lives to this treatment.

The amount of strychnine sulphate in the first of these cases was equivalent to 400 mg., or about four times the ordinary fatal dose, by mouth. However, recovery from doses of this magnitude have been reported by the older methods of treatment.[8] Dawson and Taft[9] found that this antagonism is shared by other barbiturates. With subcutaneous injection, strychnine sulphate is generally fatal to rabbits in the dosage of 0.6 mg. per kilogram. Administering double this fatal dosage, they then injected various barbiturates by vein "immediately with the onset of convulsions, and repeated as judged necessary to control their recurrence." All the treated animals survived, the necessary dosage of the barbiturate being, for pentobarbital, 14 mg.; for amytal, 15 mg.; for phenobarbital, 30 mg.; for pernocton, 40 mg.; for sodium barbital, 150 mg.; and for chloral, 220 mg.

Swanson[10] has found that the intravenous injection of sodium amytal, 50 mg. per kilogram in a single dose, given simultaneously with the strychnine, saved rabbits from seven times the fatal dose (4 mg.) of strychnine sulphate, hypodermically.

A little more recently, Haggard and Greenberg[11] compared the antidotal potency of magnesium sulphate, apomorphine and sodium phenobarbital, administered intraperitoneally, chiefly on rats. Magnesium, with the doses used, did not diminish the fatality; apomorphine antagonized only slightly more than twice the fatal dose, but phenobarbital saved from five times the fatal dose of strychnine. The required dosage of the barbital would have been fatal to normal animals, so that the strychnine is also somewhat antagonistic to barbital poisoning. The phenobarbital also saved dogs from four times the fatal dose of strychnine.

In the meantime, Barlow,[12] as reported in this issue of The Journal, had started to extend the observations of Dawson and Taft to higher dosages of strychnine, as a demonstration experiment on antagonism. By rendering the dosage flexible, injecting pentobarbital intravenously, in rather moderate dose, 10 to 12 mg. (about one fifth of the minimum fatal dose) with the first convulsion and repeating this injection whenever strong convulsions recurred, rabbits could be saved from as much as thirty-five times the fatal hypodermic dose of strychnine; above twenty fatal doses of strychnine, however, the required quantity of pentobarbital, which increases with the dose of strychnine and reaches seven to ten doses of the barbital at that point, becomes so high that half or so of the animals, above this dosage, are killed by the barbital, the antagonism of strychnine against barbital being much less effective than that of barbital against strychnine.

The fractional intravenous injection of pentobarbital has not been tried in clinical poisoning. Barlow suggests the dosage of one-tenth grain (0.006 Gm.) of sodium pentobarbital per pound of body weight, for the first injection, and one half of this dosage (one-twentieth grain per pound) whenever convulsions recur. Caution should be used if more than four injections are given during the first two or three hours. This dosage is within safe limits and could probably be increased with little risk, if necessary.

### SPERMINE

When a drop of fresh semen is mounted on a microscope slide and allowed to stand, characteristic crystals appear in due time. These are now known to be the phosphate of spermine, a long known base, which can itself be obtained in crystalline form. The phosphate crystals were first noticed by the father of modern microscopy, Leeuwenhoek, in 1678. About a century later, in 1791, Vauquelin assumed that they were calcium phosphate. Toward the end of the last century, Poehl reported that he had isolated spermine phosphate from the testis and other organs. He believed that spermine is an essential hormone of the testis and endeavored to exploit his theory commercially, but without any long continued success. Meanwhile, the base spermine has been isolated from many organs of both the male and the female, so that it cannot be regarded as essentially specific to the male gonads.[1] This was further accentuated when spermine was found to be absent from bull's semen.[2] Investigations by Harrison[3] at St. Bartholomew's Hospital, in London, present additional evidence that spermine is not essential to the process of fertilization. It confirms the widespread distribution of the base in all sorts of tissues; but the noteworthy observation is that it is more abundant in the prostate than in any other parts examined. The prostate consists approximately of two parts of muscle and one part of glandular tissue. If it may be assumed that most of the spermine is derived from the glandular portion of the gland, the yield of 130 mg. per hundred grams of whole gland found by Harrison represents a yield of from 300 to 400 mg. per hundred grams of glandular tissue; in other words, it makes it likely that the main part, if not the whole, of the spermine of human semen is derived from the prostatic secretion. The bull does not possess a true functional prostate but only a rudimentary collection of compound acinous glands, which are regarded as the equivalent of the human prostate. This may account for the absence of spermine from the semen of that species. Incidentally, it now seems likely that some of the heterogeneous nitrogenous substances isolated from various tissues by biochemists in the course of the years are identical with spermine. This is true of "musculamine," prepared by Etard and Vila from muscle in 1902; "neuridine," obtained by Brieger from fresh human brain in 1885, and "gerontine," described in liver by Grandis in 1889. The so-called Charcot-Leyden crystals in feces are probably spermine phosphate.

### FADS IN SCIENCE

In his address as retiring president of the Botanical Society of Washington, D. C., Dr. Neil E. Stevens [1] recently discussed fads as a factor in botanical publications. The Journal has repeatedly emphasized the manner in which a new note struck in the medical field becomes a stimulus to the publication of vast numbers of articles along that line. Typical examples are, of course, the discussions on medical versus surgical treatment of peptic ulcer, focal infection, parasitology, and the vaccine treatment of disease. Every one knows that medicine has passed through epochs of major interest in physiology, in the pathology of the cell, in bacteriologic investigation, in biochemistry, in hydrogen ion concentration, and at the present moment in colloids and in allergy. Associated with the development of any such major interest comes a new vocabulary in which words are developed and frequently used even by men of science almost as magical symbols rather than as scientific terms. The analysis by Dr. Stevens of the fads in the field of botany has many analogies in medical thought. He refers, for instance, to the keywords of 1906 and 1908, such as "physiologically balanced solutions" and "antagonism." In botany also the hydrogen ion concentration has been having its day. "Just as a man in good general health who consulted a physician between 1910 and 1920 was predestined to be diagnosed as having appendicitis," says Dr. Stevens, "so a plant which showed any unusual abnormality between 1915 and 1925 was sure to be under suspicion of having some mosaic disease." Fashions have their advantages exactly as they have their disadvantages. No doubt, both men and women are better off with cigarets than with chewing tobacco. What would have happened had the cigaret failed to appear and had womankind taken up the masculine prerogative of chewing? The idea makes one aghast. The fad disappears almost invariably through two causes: First, the plethora of literature swamps the reader and forces him into new lines of thought. As Prof. S. W. Williston says, "It is easier to pick up a new line than to master the literature of an old one." Second, out of each of the fads that is developed there remains some residue of actual knowledge and progress for mankind without which, no doubt, progress would stop. A philosophical consideration of this kind offers stimulus to medical reason and explains many great trends in medical practice.

### MEDICAL BROADCAST FOR THE WEEK

### American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 1:30 to 1:35 p. m. over Station WBBM (770 kilocycles, or 389.4 meters) of the Columbia Broadcasting System. The Columbia chain program has been discontinued for the present.

The program for the week is as follows:

June 6. Food and Food Advertising.
June 8. Looking Ahead to Hay Fever Time.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 11:15 to 11:30 over Station WBBM.

The program for the week is as follows:

June 11. Infantile Paralysis.

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time.

## *Medical News*

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

### ARIZONA

**Medical Library Opened.**—The Maricopa County Medical Society has recently opened a library in a new professional office building in Phoenix. Medical journals and books have been lent by members of the society and by *Southwestern Medicine* and a part time librarian has been engaged. The society has invested about $1,000 in library equipment.

### CALIFORNIA

**Study of Heredity in Twins.**—Samuel J. Holmes, Ph.D., professor of zoology, University of California, Berkeley, is directing a study of the manifestations of tuberculosis, cancer, mental defect and insanity in twins, and especially identical twins, as a possible means of throwing light on the rôle of heredity in causing such diseases and defects. Professor Holmes would appreciate information from physicians concerning patients or acquaintances who suffer from any of these afflictions.

**Personal.**—Dr. Wilfred H. Kellogg has been made chief of the bureau of food and drugs, in addition to his duties as chief of the division of laboratories, California Department of Public Health.——The following three appointments to the state board of medical examiners were announced, May 3: Drs. William R. Molony, Los Angeles, to succeed Harry V. Brown, Glendale; Fred R. De Lappe, Modesto, to succeed George Dock, Pasadena, and Charles T. Sturgeon, Los Angeles, to succeed Herbert M. Robertson, Santa Ana.——Dr. Herbert M. Evans, director of the Institute of Experimental Biology of the University of California, has recently been elected to membership in the Kaiserlich-Leopoldinischen Deutschen Akademie der Naturforscher, in recognition of his outstanding investigations in the field of vitamins.

### COLORADO

**Society News.**—Dr. Charles J. Singer, professor of the history of medicine, University of London, London, England, addressed the Medical Society of the City and County of Denver, May 17, on "Transition from Medieval to Modern Times."

**License Restored.**—At a meeting of the state board of medical examiners, the license of Dr. Hall H. Thomas to practice medicine and surgery in Colorado was restored. Dr. Thomas's license had been revoked, July 7, 1931, after he was found guilty of unprofessional and dishonorable conduct in having an unlicensed practitioner associated with him in the practice of medicine.

---

[1] Stevens, N. E.: The Fad as a Factor in Botanical Publication, Science 75: 499 (May 13) 1932.

## CONNECTICUT

**Society News.**—At a meeting of the Stamford Medical Society, April 12, the speakers were Drs. Arthur H. Ruggles, Providence, R. I., on "Neurosis in General Practice"; Clarence O. Cheney, New York, "Psychiatry in the Community," and Clarence G. Bandler, New York, "Newer Treatment of Prostatic Obstruction."

**County Society's Annual Meeting.** — The one hundred and fortieth annual meeting of the Hartford County Medical Association was held in Hartford, April 5. Dr. Robert S. Buol, New Britain, presented a case of pyloric stenosis; Dr. Frank A. Pemberton, Boston, "Recent Developments in Gynecology," and Dr. Herbert Thoms, New Haven, Conn., "Recent Developments in Obstetrics." Entertainment included a buffet supper and smoker. Dr. Henry F. Stoll, Hartford, was elected president at this meeting, and Dr. Stanley B. Weld, Hartford, reelected secretary.

**Rabies Prevalent.**—The Connecticut department of health in its weekly bulletin, May 23, reported that rabies among dogs is now prevalent in the state. Since the first of January, fifty-seven dogs have been found to have rabies as compared with a total of sixty-three for the year 1930, which was the highest total in fourteen years. Other high years were 1927 and 1931 with fifty-six cases reported for each year, and 1926 with fifty-four. Low years were 1920 with only four cases and 1924 with five cases. At the present time, the report continues, twelve towns in Connecticut are under dog quarantine, which means that dogs not vaccinated against rabies are not permitted to roam at large. Cases of rabies have been reported from thirty-six towns since the first of the year.

## ILLINOIS

**Licenses Revoked and Suspended.** — David Andrew Stevens' license to practice medicine in Illinois was revoked by the state department of registration and education, May 12. Stevens entered the California state prison at San Quentin, April 18, 1931, to serve two indeterminate sentences, one not to exceed fifteen years and the other from one year to life, the sentences running consecutively. Stevens' California license was revoked, July 9, 1931, because of his conviction of a statutory offense. He must serve at least two calendar years before his parole application can be considered. On May 18, the department suspended for three months the medical license of Dr. Ethel Maria Fikany, Chicago. She was formerly associated with Lester Tilton, the cancer "specialist," who is now on trial for conspiracy to violate the medical practice act.

### Chicago

**Society News.**—Officers of the Chicago Tuberculosis Society for the ensuing year are Drs. Minas Joannides, president; Ellis B. Freilich, vice president, and Otto C. Schlack, secretary.——The first Joseph A. Capps Prize paper was read by Dr. Warren B. Matthews, May 27, before the Institute of Medicine of Chicago on "Studies on the Etiology of Gastric and Duodenal Ulcer." The prize was presented to Dr. Matthews at this meeting. Other speakers on the program were Drs. Otto F. Kampmeier on "Problem of Coordination of Medical Libraries in Chicago," and Frank E. Simpson, "Problems in Radium Treatment of Carcinoma and Other Radiosensitive Tumors."

## INDIANA

**Personal.** — Dr. Monroe T. Koons, Mulberry, has retired from the practice of medicine after fifty-seven years in service. ——Dr. and Mrs. Josephus Myers, Alton, celebrated their golden wedding anniversary in March. Dr. Myers, who is 81 years of age, is said to be Crawford County's oldest practicing physician.

**Society News.** — Dr. Carl E. Badgley, Detroit, among others, addressed the Elkhart County Medical Association recently in Elkhart on "Maggots in the Treatment of Osteomyelitis."——The Marshall County Medical Society was addressed at Plymouth, May 5, by Dr. Louring W. Vore, Plymouth, on "Management of the Diabetic."——At the May 9 meeting of the Randolph County Medical Society in Winchester, Dr. Fred M. Ruby, Union City, spoke on "The Medical Eye Specialist versus Optometrist."——Dr. Paul R. Boren, Poseyville, addressed the Posey County Medical Society in New Harmony, May 12, on "Anaphylactic Reaction Following Administration of Diphtheria Toxin-Antitoxin."——The Indianapolis Medical Society was addressed, May 16, by Drs. Thomas B. Noble, Jr., and Homer G. Hamer on "A New Conception of Gynecological Surgery" and "Various Causes of Perineal Swellings," respectively. Dr. Ralph M. Waters, Madison, Wis., addressed the society, May 24, on spinal anesthesia.——Dr. Thomas J. Heldt, Detroit, addressed the Madison County Medical Society, April 18, on "Newer Methods in the Treatment of General Paresis."

## LOUISIANA

**Personal.**—Dr. George S. Bel, emeritus professor of theory and practice of medicine and clinical medicine, Tulane University of Louisiana School of Medicine, New Orleans, has been appointed professor of the principles and practice of medicine in Louisiana State University Medical Center, succeeding the late Dr. James Birney Guthrie.

**Medical Center Dedicated.** — The new Louisiana State University Medical Center in New Orleans was dedicated, May 10, the ceremonies taking place on the grounds of Charity Hospital. Dr. Emmett L. Irwin was master of ceremonies, and Dr. Arthur Vidrine, dean of the medical center, made the introductory remarks. The new medical school building, which with equipment cost $1,500,000, was opened to students last fall.

**Society News.**—Dr. Cecil O. Lorio, Baton Rouge, was elected president of the Louisiana State Pediatric Society, in New Orleans, May 10; Dr. Edwin A. Socola and Dr. Maud Loeber, New Orleans, were elected vice president and secretary, respectively. Among the speakers at this meeting were Dr. Laurence R. DeBuys, New Orleans, on elevated temperatures in the new-born.——At the annual meeting of the Louisiana State Coroners' Association, May 10, Dr. Willis P. Butler, Shreveport, was elected president; Dr. Charles M. Horton, Franklin, vice president, and Dr. Luther L. Ricks, Independence, secretary.——Dr. Charles J. Bloom, New Orleans, addressed the Seventh District Medical Society, recently, on "Use of Dicalcium Phosphate in Experimental Rickets."——Dr. Clarence Pierson, Pineville, was elected president of the Louisiana Hospital Association, April 7, at its annual meeting in Alexandria. The next annual session will be held in Shreveport.

## MARYLAND

**University Observes One Hundred and Twenty-Fifth Anniversary.**—The University of Maryland celebrated the one hundred and twenty-fifth anniversary of its founding, June 3. The exercises were held in Baltimore and at College Park. Speakers included Dr. William H. Welch, director emeritus, Johns Hopkins University Institute of the History of Medicine, and John H. Finley, associate editor of the New York *Times*. Clinics were given by Dr. Raymond G. Hussey, professor of pathology, Yale University School of Medicine, and Major Norman T. Kirk, Walter Reed Hospital, Washington, D. C. Dr. Hussey spoke on "Coronary Thrombosis," and Major Kirk, "Some Phases of Amputation." Both are graduates of the school. The principal speaker at the alumni banquet was Dr. Watson Smith Rankin, Charlotte, N. C. The guests included Raymond S. Pearson, LL.D., president of the university; members of the board of regents; Dr. Randolph Winslow, professor emeritus of surgery, and Dr. Leonard E. Neale. The University of Maryland Medical School was established as the College of Medicine in December, 1807. It is the fifth oldest institution for medical education in the United States. The schools antedating the Maryland institution are the College of Physicians and Surgeons of New York, University of Pennsylvania Medical School, Harvard Medical School and Dartmouth Medical School. The University of Maryland has absorbed the Baltimore Medical College and the College of Physicians and Surgeons. It has one of the oldest medical school libraries in the country and is said to have been the first medical school to make dissection a compulsory part of its curriculum.

## MASSACHUSETTS

**License Revoked.**—At a special meeting of the board of registration in medicine, May 12, the license of Dr. William H. H. Briggs, Haverhill, was revoked because of a court conviction of having performed an abortion. At this meeting the license of Dr. James P. McCue, Hudson, was suspended.

**Personal.**—An oil portrait of Dr. Frederic A. Washburn, director, Massachusetts General Hospital, Boston, has recently been painted and presented by his friends to the hospital. The portrait is the work of Mr. Edmund C. Tarbell.——Dr. Charles Stanley Raymond, for the past three years assistant to the commissioner of mental diseases for Massachusetts, has been appointed superintendent of the Wrentham State School.

**Society News.** — Dr. Frederic Jay Cotton, Boston, addressed the Berkshire District Medical Society in Pittsfield, May 13, on "Fractures of the Ankle and Wrist."——At the annual meeting of the Suffolk District Medical Society, April 27, Dr. William H. Robey was elected president.——Dr. Charles G. Miles, Brockton, is the president for the ensuing year of the Plymouth District Medical Society. Dr. Leon A. Alley, Middleboro, was among the speakers at the annual meeting of the society, his subject being "The Sanatorium Child."——Dr. Albert Warren Stearns addressed the New England Society of Psychiatry, May 17, on "Experiences in Treatment of Crime in Massachusetts."——At the May 20 meeting of the New England Roentgen Ray Society, Dr. Byrl R. Kirklin, Rochester, Minn., spoke on "Value of the Meniscus Sign in the Diagnosis of Carcinoma of the Stomach."

**Floating Hospital.**—The *New England Journal of Medicine* reports that a custom has been adopted by the Boston Floating Hospital of naming a certain day in recognition of a gift of $200. Two days have already been named, one in memory of Robert W. and Nellie A. Milne, and the other in memory of Albert C. Smith. The donor of the sum of $200 has the opportunity of meeting the approximate cost of expenses for that day in memory of a friend or relative or to mark an anniversary, the journal reported. The Boston Floating Hospital is now known as the Jackson Memorial Building. It is a unit of the New England Medical Center. June 1, 1927, the boat called the floating hospital was burned at a loss of about $150,000, while undergoing an annual overhauling at the dock (The Journal, June 18, 1927, p. 1973). It had been in operation for several years carrying thousands of tenement children down the harbor in summer on fresh air cruises. The Boston Floating Hospital was established in 1891.

## MICHIGAN

**Society News.**—Gov. Wilber M. Brucker addressed the Wayne County Medical Society, Detroit, May 24, on "State Affairs."——The St. Clair County Medical Society was addressed at Port Huron, May 3, by Dr. John L. Chester, Detroit, on "Thyrogenic Heart Disease."——Dr. George B. Eusterman, Rochester, Minn., will address the Calhoun County Medical Society, June 7, on "Clinical and Roentgenological Consideration of Malignant Gastric and Duodenal Lesions Masquerading as Benign Disease, and Vice Versa."

**Service for Children Having Heart Disease.**—The board of education of Detroit maintains special schools and classes in various sections of the city for children afflicted with heart disease. Of 1,148 children examined during 1931, 631 were admitted for care. Of these 452 had organic heart disease. Two hundred and eleven children were admitted to classes in open air schools, and 378 to classes in open window rooms. Forty-two were cared for in the regular grades, and 146 were transported to school by the board of education. Changes were made in the clinical classification of 110 children under observation during the year; 66 improved and 44 declined. In this service, the children are either referred by private physicians or detected by routine school examinations. The department of health furnishes constant medical supervision of the classes, consisting of selection of those who are eligible for care, determination of the need for transportation, assignment to the proper class, classification according to type of disease, regulation of the activities of the children while in school, advice as to home activities, and some follow-up care after dismissal from school.

## NEW JERSEY

**Society News.**—Nine physicians who were natives of Gloucester County but have practiced elsewhere were guests of honor at a dinner given by the Gloucester County Medical Society, May 19. They were Drs. Isidor P. Strittmatter, Charles C. Wolferth, George M. Laws and Carroll F. Haines, Philadelphia; Oram R. Kline and Reuben L. Sharp, Camden; Lydia W. Stokes, Woodbury; David R. Brewer and Charles L. S. Brennan, Gloucester City.

**State Medical Meeting at Atlantic City.**—The one hundred and sixty-sixth annual meeting of the Medical Society of New Jersey will be held in Atlantic City, June 15-17, under the presidency of Dr. John F. Hagerty, Newark. The house of delegates meets the first day and the scientific sessions begin Thursday, June 16. Guest speakers listed on the program include Drs. Lewis Gregory Cole, New York, on "Pathogenesis and Repair of Gastric and Duodenal Ulcer"; George W. Mackenzie, Philadelphia, "Management of Running Ears"; Laurance D. Redway, Ossining, N. Y., "Pathology of the Living Human Eye and Its Clinical Recording by Color Photography"; Roger H. Dennett, New York, "Treatment of Chorea"; Murray H. Bass, New York, "Diagnosis and Treatment of Tuberculosis in Infancy and Childhood," and Leroy A. Wilkes, New York, "Rôle of New Jersey Physicians in the Community Health Program." A dinner dance will be given, Thursday evening. A scientific exhibit, prepared under the direction of Dr. Harrison S. Martland, Newark, will be presented.

## NEW YORK

**Report of Grievance Committee.**—Nearly 3,000 complaints of illegal practice and 201 complaints against licensed physicians were investigated during the five-year period begun January, 1927, when the Webb-Loomis bill amending the state medical practice act became a law, according to a recent report by Dr. Harold Rypins, secretary, state board of medical examiners and executive secretary of the state grievance committee. Of 2,932 cases of illegal practice, no violation was found in 1,066. Of 1,866 violations of the statute, 1,355 were stopped without criminal prosecution; 274 were prosecuted and 237 cases were uncompleted at the time of the report. Convictions were obtained in 205 of the 274 cases prosecuted, a phenomenally high percentage, Dr. Rypins pointed out. The outright practice of medicine in defiance of state law has diminished greatly during the five years. Technical violations have, on the other hand, increased. The second major object of the amended medical practice act was the creation of the grievance committee for the disciplining of physicians. In 100 cases, half the charges received, the physician complained about was exonerated. In the remaining 101 cases there was definite evidence of wrongdoing. In 41 of these, the offense was not of a nature to warrant more than a warning and only seventeen were referred to the board of regents for formal discipline. Eight licenses were revoked and two were suspended; six physicians were censured and one case was dismissed.

### New York City

**Personal.**—Dr. Abraham Flexner, for many years director of the division of studies and medical education of the General Education Board, was elected president of the board of trustees of Howard University, Washington, D. C. Dr. Flexner succeeds John H. Sherburne, LL.B., of Boston.——Dr. S. Adolphus Knopf has been appointed official delegate to represent the United States at the eighth conference of the International Union Against Tuberculosis, to be held at Amsterdam and The Hague, September 6-9.

**Arbitration Among Dentists and Dental Trades.**—Disputes arising between members of the dental profession and the dental trades in Greater New York, including laboratories, manufacturers and dealers in supplies, will hereafter be submitted to arbitration under a plan adopted, April 25, by the groups concerned, in cooperation with the American Arbitration Association. The organizations that will participate in the plan include the first and second district dental societies of New York, the Associated Dental Laboratories, Dental Exhibitors' Association and the Metropolitan Gold Club. An advisory committee made up of one representative from each of the related groups will cooperate with the American Arbitration Association in administering the plan. There will also be a special panel of arbitrators drawn from the cooperating organizations to furnish technical advice. When disputants desire the services of arbitrators not connected with dentistry, the regular panel of the association will be available. The sponsors point out that the arbitration plan will operate only when there is an actual controversy arising out of a contractual relation. When there has not been a written contract, the parties to a dispute may mutually agree to arbitration. The plan contemplates, however, that the dental trades will prepare order forms including a provision for arbitration in accordance with the rule of the arbitration association and the New York arbitration law. All arrangements for administration of the plan will be handled by the association with the help of the advisory committee when needed, according to the announcement.

## NORTH DAKOTA

**Society News.**—The Sixth District Medical Society was addressed, April 12, among others, by Drs. Paul H. Burton, Fargo, on "Backache"; Reuben H. Waldschmidt, Bismarck, "Fractures of the Humerus," and Robert W. Henderson, Bismarck, "Physiology of the Kidney."——Drs. Carl E. Elofson and Ralph E. Pray, Fargo, addressed the April meeting of the Cass County Medical Society, Fargo, on complications of pneumonia and childhood tuberculosis, respectively.——The Southwest District Medical Society held its April meeting at New England, with Dr. Albert E. Spear, Dickinson, as the speaker, on disorders of the eye.

# MEDICAL NEWS

## PENNSYLVANIA

**License Revoked.**—The Pennsylvania State Board of Medical Education and Licensure revoked the license of Dr. Modestus William S. Buechele, Altoona, to practice medicine in Pennsylvania, April 22. Dr. Buechele was convicted of violating the antinarcotic laws of Pennsylvania, but sentence was suspended on condition that he leave the state at once.

**Reports Requested on Occupational Disease.**—The state department of health of Pennsylvania requests hospitals, physicians and other persons to report all cases of anthrax, anthracosis, poisoning by aniline, arsenic, benzol, chromium, lead, manganese, mercury, dinitrobenzol and other industrial substances and silicosis. These cases should be reported to local health officers, but special reports direct to the state department are also requested. Reports of lead poisoning must also be made to the department of labor and industry. The department of health announces that increased attention is to be given to these diseases henceforth.

**Society News.**—The annual meeting of the Fifth Councilor District of the Medical Society of the State of Pennsylvania will be held at York, July 28. Drs. Elliott P. Joslin, Boston, and Eldridge L. Eliason, Philadelphia, will speak on diabetes and the surgical aspects of diabetes, respectively.——The program of the Pittsburgh Academy of Medicine, May 24, included addresses by Drs. John P. Griffith on "Treatment of Toxic Goiter"; William S. McEllroy, "Cyanosis Due to Altered Blood Pigment," and Frank H. Rimer, "Diagnosis and Treatment of Maxillary Sinusitis."——Drs. William W. Peter and Victor G. Heiser, New York, were guest speakers at the annual meeting of the Pennsylvania Public Health Association, in Pittsburgh, May 26-27. Dr. Peter's subject was "Adventures in Health Education" and Dr. Heiser's, "Health Conservation in Middle Age."——Dr. William H. Mayer, Pittsburgh, addressed the Northampton County Medical Society, Easton, May 20, on "What the Family Doctor Should Know About Mental Conditions."

## SOUTH DAKOTA

**Dr. Pohlman Appointed Dean.**—Dr. Augustus C. Pohlman, professor of anatomy, St. Louis University School of Medicine, St. Louis, has been appointed dean of the South Dakota University School of Medicine, succeeding the late Dr. George R. Albertson. Dr. Pohlman will also be professor and director of the department of anatomy. Dr. Pohlman was professor and director of the department of anatomy at St. Louis University School of Medicine from 1913 to 1929, when he began special research on deafness. In 1930 he was made research professor of anatomy, giving up his administrative duties to continue his studies of deafness. He has held teaching positions at Cornell University, Johns Hopkins University and Indiana University. He graduated from the University of Buffalo School of Medicine in 1900.

## UTAH

**Tuberculosis Institute.**—An institute on "case finding" as a factor in the control of tuberculosis was recently held in Salt Lake City for tuberculosis workers of Washington, Arizona, Oregon, California, New Mexico, Idaho, Wyoming, Nevada, Montana and Utah. Among other speakers, Drs. Iago Galdston and Harry E. Kleinschmidt, New York, led discussions on "Pathology and Epidemiology of Tuberculosis" and "Methods and Machinery of Case Finding," respectively. Drs. Galdston and Kleinschmidt and Dr. Kendall Emerson, also of New York, addressed the Salt Lake County Medical Society at its regular monthly meeting.

## VIRGINIA

**University News.**—Dr. Frank L. Apperly, until recently a member of the department of pathology, University of Melbourne, has been appointed professor of pathology at the Medical College of Virginia, Richmond. Dr. William D. Cutter, secretary, Council on Medical Education and Hospitals, American Medical Association, Chicago, delivered the commencement address of the college, May 31.

**Dr. Lapham to Direct Prenatal Work.**—Dr. Maxwell E. Lapham, Philadelphia, has been selected as clinical instructor in prenatal and postnatal work, which is to be conducted under the sponsorship of the Medical Society of Virginia. This activity is a recent expansion of the society's graduate work. It will include review, instruction and clinical demonstration for practitioners of the state. Dr. Lapham was formerly an instructor in obstetrics at the University of Pennsylvania Medical School.

**Society News.**—Dr. Earl B. McKinley, Washington, D. C., addressed the Richmond Academy of Medicine, April 26, on "The Filtrable Viruses and Bacteriophage" and Dr. J. B. Dalton, on "Care of the Weak Foot."——Dr. Austin I. Dodson, assistant professor of genito-urinary surgery at the Medical College of Virginia, Richmond, has been promoted to the professorship to succeed Dr. Robert C. Bryan, who recently retired.——At a recent two day meeting of the Southwestern Virginia Medical Society in Bristol, the following program was given: Drs. Warren F. Draper, Richmond, state health commissioner, "Matters of Current Interest in Medicine and Public Health"; Isaac C. Harrison, Danville, "Responsibilities of the General Practitioner in the Field of Preventive Medicine"; Arthur D. Hutton, Marion, "Clinical Laboratory as an Aid in the Diagnosis, Treatment and Prognosis of Diseases"; Linwood D. Keyser, Roanoke, "Transurethral Resection of the Prostate"; Elbyrne G. Gill, Roanoke, "Esophageal Stricture"; Temple S. Fay, Philadelphia, "Intracranial Pressure and Its Relation to Modern Problems of Medicine"; Walter C. Caudill, Pearisburg, "Meckel's Diverticulum: Report of Case with Ulcer and Perforation"; Marcellus A. Johnson, Jr., Roanoke, "Trauma," and Roger H. DuBose, Roanoke, "Some Common Causes of Anorexia in Children."

## GENERAL

**National Board Meeting.**—At the annual meeting of th National Board of Medical Examiners in Washington, May 2 Dr. Waller S. Leathers, Nashville, Tenn., was reelected president for the ensuing year; Mr. Everett S. Elwood, Philadelphia, was reelected executive secretary, and Dr. John S. Rodman, Philadelphia, reelected medical secretary. Reports for the year showed an increase in the total number of candidates examined, and a total of 1,035 new applications for admission to Part I as compared with 973 in the previous year. The total number of states now recognizing the board's examinations is forty-one, besides the territories of Porto Rico, Hawaii and the Canal Zone.

**Society News.**—Dr. Alvin G. Foord, Pasadena, Calif., was named president-elect of the American Society of Clinical Pathologists and Dr. Walter M. Simpson, Dayton, Ohio, became president at the annual meeting in New Orleans, May 6-9. The Burdick Award was given to Dr. Benjamin S. Kline, Cleveland, for his contribution on serological diagnosis of syphilis. Dr. Roy R. Kracke, Decatur, Ga., received the society's gold medal for an exhibit on agranulocytic angina.——Dr. Frank Smithies, Chicago, was elected president of the American Therapeutic Society at the annual meeting in Baltimore, May 16-17. Dr. Oscar B. Hunter, Washington, D. C., is secretary.——Dr. Fred Wise, New York, was elected president of the American Dermatological Association at the annual meeting in Havana, Cuba, May 3-5.

**Another Four Weeks of Automobile Fatalities.**—The U. S. Department of Commerce announces that during the fou weeks ended May 14 eighty-five large cities in the United States reported 564 deaths from automobile accidents, as compared with 688 deaths during the four weeks ended May 16, 1931. Most of these deaths were the result of accidents which occurred within the corporate limits of the city, although some accidents occurred outside the city limits. For the fifty-two week periods ended May 14, 1932, and May 16, 1931, the totals for all the cities were, respectively, 8,832 and 9,097, which indicate a recent rate of 24.6 per hundred thousand of population as against an earlier rate of 26. Eight cities reported no deaths from automobile accidents for the last four weeks, while three cities reported no deaths from automobile accidents for the corresponding period of 1931.

**Public Health Meeting.**—Three subjects of major importance in the West will be discussed at the third annual meeting of the Western Branch of the American Public Health Association, which will be held in Denver, June 9-11. Psittacosis, now apparently endemic in native western birds of the parrot family, will be discussed by Karl F. Meyer, Ph.D., San Francisco; Rocky Mountain spotted fever, with special reference to its relation to typhus, by Dr. Robert H. Riley, Baltimore; and reciprocal relations for control of shell fish in Pacific ports, by Drs. Giles S. Porter, Sacramento, Calif.; Frederick D. Stricker, Portland, Ore., and Albert E. Stuht, Seattle, state health officers. Other speakers will be Drs. Eugene L. Bishop, Nashville, Tenn.; Mazyck P. Ravenel, Columbia, Mo., and John A. Ferrell, Kendall Emerson, New York; Michael M. Davis, Ph.D., Chicago, and Louis I. Dublin, Ph.D., New York.

**Medical Bills in Congress.**—*Changes in Status:* H. R. 11082 has been reported unfavorably to the House, proposing to liberalize existing restriction relative to the dissemination of information and devices for the prevention of conception

(H. Rept. 1435). The committee report said, in part: "This is a very controversial matter; and in these times of economic unrest and discontent, with the necessity upon Congress of giving its undivided attention to public matters of the highest importance, the committee reaches the conclusion that it is unwise at this time to inject a discussion of this matter into the House and country." H. R. 10236, the revenue bill, is still before the Senate. On May 26, the Senate specifically exempted "frames or mountings for spectacles or eyeglasses" and "surgical instruments" from the section proposing a tax of 10 per centum on jewelry, which section was reinserted in the bill after having been stricken therefrom by the Senate Committee on Finance.

**Results of Special Board Examinations.**—Forty-four candidates took the examination of the American Board of Otolaryngology in New Orleans, May 9; thirty-seven passed and seven failed. The next examination will be held in Montreal, September 17. New requirements for candidates will go into effect after the Montreal examination, according to Dr. Harris P. Mosher, Boston, president of the Board, as follows:

1. A candidate acceptable for the examination must be a graduate of an approved medical school with at least one year of approved internship or three years of general practice.
2. In addition, a candidate must have completed an academic year as a basic course in otolaryngology or one year of internship in otolaryngology followed by two years of specialized practice.
3. Five years of specialized practice will be accepted in lieu of the requirements of paragraph 2.

Fifteen applicants took the examination of the American Board of Obstetrics and Gynecology in New Orleans, May 10, with three failures.

**Winners of Annual Golf Tournament.**—Dr. John Welsh Croskey, Philadelphia, was elected president of the American Medical Golfing Association following the eighteenth annual tournament and dinner in New Orleans, May 9. Drs. Homer K. Nicoll, Chicago, and James P. O'Kelley, New Orleans, were elected vice presidents. The names of winners of the various events follow:

Dr. Samuel M. Hill, Dallas, Texas, association championship: the Will Walter Trophy, with a low gross score of 161 for thirty-six holes.
Dr. Alonzo C. Smith, Wooster, Ohio, handicap championship for thirty-six holes: the Detroit trophy.
Dr. John P. Loudon, Yakima, Wash., the thirty-six hole choice score handicap championship: the St. Louis trophy.
Dr. John L. Lattimore, Topeka, Kan., low gross eighteen hole championship: the Golden State trophy.
Dr. Harry H. McClellan, Dayton, Ohio, low net eighteen hole championship: the Ben Thomas trophy.
Dr. John P. Dewitt, Canton, Ohio, the "maturity event," limited to Fellows more than 60 years old: the Minneapolis trophy.
Dr. Edwin G. Zabriskie, New York, the "old guard" championship, limited to past presidents of the golfing association: the Wendell Phillips trophy.
Dr. Robert C. Jamieson, Detroit, the "kickers handicap": the New Orleans trophy, donated by Mayor T. S. Walmsley of New Orleans.
Dr. Jacob R. Rupp, Detroit, the consolation event.

**Grants of Commonwealth Fund.**—Clinical instruction in prenatal and postnatal care will be provided for Virginia physicians in the coming year through a grant of $10,000 to the Medical Society of Virginia by the Commonwealth Fund. The grant, which has a reservation of $5,000 for next year and is conditioned on the appointment of a satisfactorily qualified clinician, represents an extension of the fund's established activities in graduate education for physicians, since the medical society takes the initiative and direct responsibility in a project for improving the practice of its members. The fund, at its April meeting, also made appropriations to continue the study of dental decay at Columbia University School of Dental and Oral Surgery; to continue the development of rural public health service in New Mexico (where the fund is helping the state health department to provide public health nursing in fourteen counties); to enable pediatricians to attend the Southern Pediatric Seminar, and to continue the study of the effectiveness of current technic in preventing the spread of diphtheria and scarlet fever, under direction of the American Public Health Association. The sum of $143,720 was appropriated to the Division of Rural Hospitals for the coming year, with a provision for special assistance to the state health department of Maine in organizing town-unions for public health similar to those already set up in the Nashoba and Southern Berkshire districts in Massachusetts and in process of formation in the district surrounding the hospital at Farmington, Maine. An appropriation of $61,140 was made to carry the fund's mental hygiene service in Great Britain through another year.

**Bequests and Donations.**—The following bequests and donations have recently been announced:

St. Joseph's Hospital, Philadelphia, $5,000 by the will of the late Patrick J. Lawler.

Woodford County Memorial Hospital, Versailles, Ky., $20,000 by the will of Col. John C. Durrett.

Shriners Hospital for Crippled Children, Philadelphia, and the Children's Seashore House, Atlantic City, N. J., each $1,000 by the will of the late Catharine Royal Shellenberger.

Bethesda Home, St. Louis, $5,000, and German Protestant Orphan Asylum, Barnard Free Skin and Cancer Hospital, St. Louis, each $2,000 by the will of Mrs. Gussie L. Grenner.

American Dormitory of the Cité Universitaire of Paris, $50,000 to be devoted to the creation of scholarships for young medical students and students of music and composition, by the will of the late Harriet Hale Wooley.

Mount Sinai Hospital, New York, $10,000 by the will of Rosalie Hyams.

Woman's Medical College of Pennsylvania, Philadelphia, $10,000 by the will of the late George Taylor.

Hospital of St. Barnabas, Newark, N. J., $5,000 by the will of Rev. Melvin Honeyman.

Mary Hitchcock Memorial Hospital, Hanover, N. H., $120,000 by the will of Charles N. Vilas, New York.

Children's Hospital, Boston, Hospital for Joint Diseases, New York, each $5,000 by the will of Mrs. J. L. Hanna.

Woman's Hospital, New York, $10,000 by the will of Dr. James Riddle Goffe.

St. Luke's Hospital, New York, $88,000, and New York Eye and Ear Infirmary, $30,000 by the will of Mrs. M. B. Caswell.

Presbyterian Hospital, Chicago, $25,000 by the will of the late John W. Scott.

Holmes Memorial Hospital of the University of Cincinnati, Cincinnati, $3,000 by Mrs. Christian R. Holmes to establish an ophthalmic unit.

Boston Home for Incurables, Boston, and Children's Hospital, Boston, each $2,000 by the will of the late Dr. William Appleton.

Sydenham Hospital, New York, $2,500 by the will of the late Simon Sichel.

St. Vincent's Hospital and St. Joseph's Hospital for Consumptives, New York, each $50,000 by the will of the late Dr. John B. Manning.

Babies' Hospital, Memorial Hospital for the Treatment of Cancer and Allied Diseases and New York Post-Graduate Medical School and Hospital, all of New York, $10,000 each by the will of the late William Fitz Randolph.

Presbyterian Hospital, New York, $15,000 by the will of Miss Ida Adams.

Margaret Pillsbury Hospital, Concord, N. H., $10,000 by the will of Mrs. Ella Hoppin.

## CANADA

**Balfour Lecture.**—Dr. Rudolph Matas, emeritus professor of surgery, Tulane University of Louisiana School of Medicine, New Orleans, delivered the sixth annual Donald C. Balfour Lecture at the University of Toronto Faculty of Medicine, April 5, on "The Story of Postoperative Pulmonary Embolism Before and After Lister." The date was the one hundred and fifth anniversary of the birth of Lord Lister.

**Silver Jubilee.**—The Toronto Academy of Medicine celebrated its silver jubilee, April 7, with a banquet at the King Edward Hotel, after which Dr. Archibald Malloch, librarian of the New York Academy of Medicine, New York, made an address on Sir William Osler. Papers on the history of the academy were read by Drs. Edward S. Ryerson and Harry B. Anderson. Miniatures of the presidential badge of office were presented to past presidents of the academy.

**Society News.**—Drs. Duncan Campbell Smyth and Alexander Stewart Macmillan, Boston, addressed the Toronto Academy of Medicine, March 1, on "Bronchoscopy as an Aid in the Diagnosis and Treatment of Pulmonary Conditions" and "X-Ray Diagnosis of Diseases of the Esophagus," respectively.——The American Pharmaceutical Association will hold its annual meeting jointly with the Canadian Pharmaceutical Association in Toronto, August 22-27.——Drs. J. W. Thomson and Archibald W. Hunter addressed the Vancouver Medical Association, April 5, on "Emergencies in Abdominal Surgery" and "Diagnosis and Treatment of Some Urological Emergencies," respectively.——The Canadian Public Health Association and the Ontario Health Officers' Association held a joint annual meeting, May 25-27.——The annual Lister Day celebration was held, April 5, at the University of Manitoba, Winnipeg, with Dr. William A. Gardner as the orator.

**Annual Meeting of Canadian Medical Association.**—The sixty-third annual session of the Canadian Medical Association and the fifty-second annual meeting of the Ontario Medical Association will be held in Toronto, June 20-24, with headquarters at the Royal York Hotel. Speakers at a public meeting, June 24, will include Drs. George W. Kosmak, New York, and James H. Mason Knox, Jr., Baltimore, on "Maternal Welfare" and "Infant Welfare," respectively. Included among the speakers are Drs. Ralph Noble, New York, on "Relationship of Psychiatry to General Medicine"; Daniel F. Jones, Boston, "Cancer of the Rectum"; Conrad Berens, New York, "Motor Anomalies in Relation to Prescribing Lenses"; Ralph M. Tovell, Rochester, Minn., "Spinal Anesthesia"; George H. Whipple, Rochester, N. Y., "Pigment Metabolism and Anemia Problems," and Donald C. Balfour, Rochester, Minn., "Variabilities in Duodenal Ulcer." There will be symposiums on cancer, collecting antiques of medical interest, and bronchiectasis. Dr. Francis R. Packard, Philadelphia, will deliver the Osler Oration, June 22, on "William Osler in Philadelphia and the School in Which He Taught."

## FOREIGN

**Congress on Biliary Lithiasis.**—Physicians who wish to present papers at the International Congress on Biliary Lithiasis to be held in Vichy, France, September 19-22, must notify the general secretariat, 24 Boulevard des Capucines, Paris, before July 1, according to an announcement. Prof. Paul Carnot is president of the congress and among the honorary presidents are Dr. Charles Gordon Heyd, New York, and Lord Moynihan of Leeds, London. Dr. Frank Smithies, Chicago, is president for the United States. Three topics have been chosen for discussion in general sessions as follows: sequelae of cholecystectomy, medical and mineral water treatment of the gallbladder in biliary lithiasis, and gallstones in the liver. In addition there will be four sections, in which shorter papers will be presented. The latter may not exceed three pages of forty lines each, while the papers for the general sessions may be ten pages long. The sections will be medicine, surgery, therapeutics and hydrology, and electroradiology and physical therapy. The official program and information concerning steamship and hotel accommodations may be obtained from Dr. Frank Smithies, 920 North Michigan Avenue, Chicago. The general secretary is Dr. J. Aimard, Paris.

**Centenary Meeting of British Medical Association.**—The one hundredth anniversary of the founding of the British Medical Association will be celebrated at the annual session in London, July 21-30. The annual representative meeting will be held July 21 and the three following weekdays, while the scientific sections will meet July 27-29. The annual general meeting will be held, July 23, at the British Medical Association House in London, and the incoming president, Lord Dawson of Penn, will deliver his address at a meeting, July 26. There will be a pilgrimage to Worcester, Sunday, July 24, to unveil two memorials to Sir Charles Hastings, founder of the association (THE JOURNAL, Dec. 5, 1931, p. 1718). Among subjects for discussion listed are "Clinical Application of the Recent Work on Bone Diseases," "Menace of Quackery in Physical Medicine," "Skin Diseases in Relation to Industry," "Immunologic Basis of Prophylactic Inoculation Against Bacterial Diseases," "Treatment of Inflammatory Conditions by Radiation," "Serum Treatment of Pneumonia," "Use of Nonspecific Protein Therapy," and "Mental Health and the General Practitioner." Among other participants in the discussions will be Drs. Russell L. Cecil, New York; Leroy U. Gardner, Saranac Lake, N. Y., and Charles MacFie Campbell, Boston. The annual popular lecture will be given, July 29, by Prof. Julian S. Huxley, Highgate, London. Dr. William George Willoughby, Eastbourne, is the present president of the association.

# Government Services

### First Woman Surgeon in Public Health Service

Dr. Estella Ford Warner has been appointed a surgeon in the U. S. Public Health Service. This is the first time in the history of the public health service that a woman has held this rank, the New York *Times* reports. Dr. Warner will tour the country in the interest of child hygiene work, study the methods of state, municipal and school health authorities and recommend improvements, with the object of making a report on the proposed coordination of child health work throughout the country. In 1928, Dr. Warner was appointed director of the Marion County (Oregon) Child Health Demonstration of the Commonwealth Fund, succeeding Dr. William DeKleine. She had been pediatrician of the demonstration since 1925. Previously she was medical director of the bureau of child hygiene of the Oregon State Board of Health. She held a similar position with the Portland board of health, and was for six years lecturer in child hygiene at the University of Oregon. Dr. Warner graduated from the University of Oregon Medical School in 1918.

### U. S. Public Health Service

Dr. Charles L. Williams was commissioned as senior surgeon in the regular corps of the public health service to rank from May 23; Asst. Surg. Thomas B. McKneely, relieved at New Orleans and assigned at marine hospital, Fort Stanton, N. M.; A. A. Surg. Charles O. Absher, relieved at marine hospital, Fort Stanton, and assigned at marine hospital, San Francisco.

### Public Demands Reduction of Road Accidents

In spite of the new road traffic act, the appalling death toll of the roads continues without sensible diminution. The public and the press cry out that something more must be done, but no one seems able to suggest anything that will make much difference. In the House of Commons the home secretary, Sir Herbert Samuel, said that the police did all they could to prevent dangerous driving but that the figures showed an exceedingly bad state of things. In Great Britain in 1931 no fewer than 6,691 persons were killed and 202,119 injured in street accidents. Every day of the year eighteen people were killed and 553 injured. The only favorable feature was that last year the number of fatal accidents was 614 less than in the previous year, but, on the other hand, the nonfatal accidents were increased by 24,224.

The subject was discussed also at the National Safety Congress, organized by the National Safety First Association. Mr. Pybus, minister of transport, said that he could see the effect of the association in the prevention of accidents in factories. But was the incredible story of death to continue unabated on the roads? In addition to the figures given for the whole country, the following were given for London. In 1931, 1,325 persons were killed in the streets, as against 1,398 in 1930, a reduction of 5.2 per cent, as against a reduction of 8.5 for the country as a whole. But closer examination revealed the startling fact that decrease of seventy-three in the London deaths was accounted for almost entirely by the fact that sixty-seven fewer motor cyclists and pillion riders were killed, indicating that the motor cycle was being less used in the metropolitan area. As against the 8.5 decrease in deaths throughout the country must be set the following: 1. There has been a reduction of about 3.2 per cent in the number of vehicles licensed to operate on the roads. 2. The number of persons injured has increased by 13.5 per cent. The returns for London for the first three months of 1932 are most disquieting. The number of persons killed has increased from 289 in the corresponding quarter of last year to 314, and the injured have increased from 9,943 to 10,865. The deputy secretary to the ministry of transport, in deploring these figures, said that he did not think that more could be done by increasing penalties or further penal legislation. What was needed was that public opinion should be roused and insist that the reckless driver who had endangered lives should receive adequate punishment.

In the House of Lords, Lord Buckmaster introduced a bill to amend the new road traffic act. His bill would enable the judge to adjust the degree of punishment to the degree of negligence. It provided that if a man killed a person by negligent driving he would be guilty of manslaughter, and if a driver knocked down or injured a person and drove straight on (as is often done) that would be a criminal offense. His bill also provided that no truck that exceeds 5 tons in total weight shall exceed the speed of 5 miles an hour in any city, town or village. He would rather cross blindfolded the railway level crossings than some of the roads as he knew them today.

The lord chancellor and other legal lords expressed appreciation at the proposal to alter the English law of manslaughter, which had existed for centuries and drew a distinction between civil and criminal negligence. The Earl of Plymouth, representing the government, expressed sympathy with the object of the bill. The government was fully alive to the gravity of the position, but he was convinced that the bill would not attain its object. If passed, "manslaughter" and "unlawful wounding" would mean something entirely different when the driver of an automobile was concerned than in any other circumstances. One of the chief impediments to a substantial reduction in the terrible toll of deaths was the reluctance of magistrates and juries to convict in cases of dangerous driving. To increase the penalties might only increase the reluctance. The government had the warmest sympathy with Lord Buckmaster's object but did not think that the bill would do anything to attain it. The bill was read a second time, without a division, showing that the house was not in sympathy with the government's do nothing policy.

### Neanderthal Man in Palestine

Three adult skeletons of Neanderthal type have been found in Palestine by the joint expedition of the British School of Archeology in Jerusalem and the American School of Prehistoric Research. They were in a small rock shelter at the western foot of Mount Carmel, which was thickly strewn with implements of Mousterian type and animal bones and bore only slight traces of later occupation. The discovery is of great importance in view of the scarcity of Neanderthal remains outside Europe. Last year a young American student, Mr. T. MacCown, found a skeleton of a 2-year child of Neanderthal type in the same cave. This is now in the Museum of the Royal College of Surgeons, London, for comparison with casts of the Neanderthal skull, known as the Galilee skull, which was discovered in 1925. The only relatively complete adult Neanderthal skeletons have heretofore been found in France. Sir Arthur Keith regards the discoveries as of the highest interest and thinks that they may throw entirely fresh light on the relations of modern man to the Neanderthal type. While the front of the child's skull is of Neanderthal type, the back is of an entirely new type, more resembling that of modern man and not akin to that of the Neanderthal man of Europe. While changes of growth might considerably alter this, it is noteworthy that the child's skull from Gibraltar is purely Neanderthal. Thus the Palestine skull may represent a new type of man in a transient stage. Neanderthal man became extinct in Europe at least 20,000 years ago, and it seems probable that the Palestinian remains are older.

### Production of Carbon Monoxide from Paint

Certain air spaces in ships and other places may remain sealed over long periods of time. Among them are the double bottoms and "bulges" or "blisters" of warships, made as a defense against torpedo attack. When such spaces have been opened for inspection or repainting, men have entered them and death has resulted. The cause is generally asphyxia. Carbon monoxide poisoning has been erroneously invoked, as the skin in such cases of acute asphyxia often remains pink. But, in the majority of cases, spectroscopic examination of the blood does not reveal any trace of carbon monoxide. Chemical analysis of the air of such spaces has shown that they may contain less than 2 per cent of oxygen without any proportional rise in the carbon dioxide content. It has long been known that the linseed oil of the paint absorbs oxygen. In the *Journal of Industrial Hygiene,* Dudding, Dudley and Frederick of the Royal Naval Medical School have shown that the air of such spaces may contain as much as 0.2 per cent of carbon monoxide. Experiments made to determine its origin showed that the iron oxide paint used in ships' bulges, which is stored sealed for various periods, may contain percentages of carbon monoxide ranging from 0.08 to 0.27. The constituent of the paint responsible for this gas is the boiled linseed oil. Chemical analyses of air taken from a bulge showed 1.3 per cent of oxygen and 0.03 of carbon monoxide. The percentage of carbon monoxide, in an atmosphere containing the ordinary amount of oxygen, which will cause dangerous symptoms in man, is laid down as from 0.15 to 0.2 per cent. It might therefore be inferred that the small percentage of carbon monoxide found in these spaces is of only academic interest, as a man entering would be asphyxiated before he could be poisoned with carbon monoxide. However, there is no constant inverse relation between the amount of oxygen and carbon monoxide in analyses of air from these spaces. This research finds application in disasters that have occurred in the United States Navy. In the *Nevada,* three men were overcome after working in a blister one and one-half hours, and there was no question as to the diagnosis of carbon monoxide poisoning. In the *New York,* nine men entered a bulge and were affected within a few minutes. Two died, and carbon monoxide was found in their blood.

### Surgery of Uterine Cancer

Professor Jean-Louis Faure recently affirmed before the Academy of Medicine that, in nine cases out of ten, cancer of the uterus is definitively curable through surgical intervention, if it is applied early enough. A few days previously, Professor Hartmann had published statistics no less optimistic on the surgical treatment of cancer of the stomach. These two surgeons are eager to defend the reputation of their art against the inroads of radiology, which is coming more and more into favor. They took occasion to point out the disadvantages of radiology. The public fears surgical operations and is more ready to resort to radium and radiography, which appear to entail no immediate risk. The radiotherapeutists have called attention to the fact that hopes based on their art were limited. These frank statements have sometimes unjustly brought surgery into discredit, which fact no doubt motivated the recent outbursts of Hartmann and Jean-Louis Faure. The latter was one of the first, in France, to attack uterine cancer by hysterectomy, applied widely, with removal of the superior portion of the vagina and the parametrium, and, especially, the use of wide Mikulicz drainage. But when the glands are involved, recurrence is inevitable. However, an early diagnosis, which is not difficult if the patient is examined at the first signs of disease, permits operating before the glands are attacked. That is the whole problem. Jean-Louis Faure affirmed that cancer of the uterus had become the most likely curable of all forms of visceral cancer. In cases in which operation is timely—that is, during the first two or three months—essential recoveries, in a series extending back several years, amounted to 83 per cent, and in a more recent series, to 96 per cent. In the total of forty-six patients operated on, there were two deaths, or 4.34 per cent; two patients were lost sight of and hence eliminated; in the remaining forty-two patients operated on there were two recurrences, or 4.54 per cent, and forty definitive recoveries, or 90.9 per cent. These results would have appeared, in an earlier day, incredible. But they can be secured only in certain cases, which, unfortunately, constitute only 1.5 per cent of patients operated on. The other cases—inoperable—which constitute most of the patients, are amenable to radium. There are still too many women who come too late to operation. Patients must be operated on early. Jean-Louis Faure said that when the general education of patients and physicians shall enable competent surgeons to operate on patients within the first two or three months, this disease, which until recently has presented such terrible aspects, will nearly always be cured. On the whole, the welfare of patients with uterine cancer is in the hands of their physicians, who should know how to diagnose a neoplasm as soon as the first signs appear.

### Changes in Tuberculosis Hospitals

Dr. Georges Petit has published a sort of manifesto in which he declares that we must modify our conceptions as to the most effective means of combating tuberculosis. Scientific

Dr. Robert [illegible] Library

reasons combine with financial considerations to point out the mistakes made and to suggest the adoption of new methods. One of the chief mistakes has been the multiplication of small dispensaries, installed with the aid of private funds. Petit considers the dispensary a useless innovation. It should no longer remain in the hands of private societies, which, in spite of good intentions, are subject to local influences, often of a political nature, which take away its independence. It should be attached to the hospital and managed by administrative boards. By doing otherwise friction is set up, or sometimes a rivalry, between the two institutions. Many dispensaries are insufficiently equipped. As a rule, the rooms are inferior. A large sum would be required to equip properly the dispensaries. The attachment to a hospital would necessitate little new equipment, and there would be a greater certainty of its proper use. This question should be judged on its own merits and unaffected by influences foreign to the object to be attained. Official statistics show the small part played by the sanatorium in the crusade against tuberculosis. As to the results, they are perverted, for several reasons. First, the sanatorium was established for fresh-air treatment, and experience has shown that fresh air alone has never sufficed to cure a tuberculous patient. This is now fully recognized, so that, in all sanatoriums, therapeutic action has regained the place that it should never have lost. Furthermore, the stay in the sanatorium is always too short to bring about more than an improvement, which is too often only transitory. However, the greatest reproach that can be brought against the sanatorium is that it receives only certain classes of patients. This weakness is serious; for, under these conditions, the sanatorium is not a general social factor, and it loses much of its utilitarian character in the crusade against tuberculosis. The sanatorium should admit all tuberculous patients. The hospital-sanatorium is, therefore, the only institution that meets he scientific conceptions and the needs of society. The great ffort to establish in the hospitals a special pavilion for the tuberculous is the beginning of a change which is widely needed and universally demanded. It is a difficult task, for there are private interests that oppose the movement; but its opponents cannot prevent the new development, for the impetus it has received is too great.

### Pediatricians Discuss Diphtheria

The Venetia Euganea chapter of the Società italiana di pediatria held recently its first regional congress at Padua, in the Clinica pediatrica, under the chairmanship of Professor Frontali. The chief topic on the program was "Diphtheria." Baccichetti discussed antidiphtheria vaccination as applied to the school children of Treviso, in 1931, 2,470 children having been vaccinated. In 105 diphtheria cases reported during the year in the commune, 6 of the patients had been vaccinated. Fifteen per cent of the children, although vaccinated, presented a positive Schick reaction. Nevertheless, the author favors making antidiphtheria vaccination compulsory, at least in collective groups of children.

Pagani-Cesa reported the results of antidiphtheria vaccination in groups of children in Padua. Of 257 children vaccinated about three years ago with three injections of Ramon toxoid, he found that only 1.8 per cent of the subjects become Schick negative. A year and a half later, he tested this group to discover how many had remained Schick positive and found the same number were Schick positive as before, showing thus that the immunization either occurs within two months from the date of the vaccination or does not occur at all. Control examinations applied, a year and a half after the inoculation, to children who became Schick negative as a result of their vaccination showed them to be still negative, proving that they had preserved their immunity. Having administered to the Schick-positive subjects a fourth injection of anatoxin, in a dose of 1.5 cc., he obtained immunization in half of the cases, showing thus that in antidiphtheritic immunization the size of the dose employed plays a part. Not one of the children vaccinated, with a Schick-negative outcome, came down with diphtheria, during two years of observation.

Denes of Padua presented some bacteriologic considerations on diphtherial sore throat. The diphtheria bacillus of the normal clinical type, which is commonly isolated in cases of pseudomembranous sore throat as clinically characterized, may show notable deviations from the norm. To these modified diphtheria bacilli belong, according to the speaker, not only the Hoffmann bacillus and other parabacilli and pseudobacilli of diphtheria, but also coccal and diplococcal types that are isolated in some forms of pseudomembranous sore throat and are hypovirulent strains due to local or general immunizing factors The speaker proposed a method for distinguishing the virulen diphtheria bacillus from the modified forms on the basis o partial staining with a 33 per cent alcohol, during the application of the Gram stain.

Golin made Schick tests on seventy children in the Clinica pediatrica of Padua, and also simultaneously made throat cultures in these cases on Löffler's medium. He found forty-five of the children Schick positive (64.28 per cent). Among the subjects examined, he found, in addition, ten healthy carriers of diphtheria bacilli (13.63 per cent), and among these 11 per cent who were Schick positive.

Cantilena of Venice pointed out that it is a common practice to use large doses of serum in the treatment of diphtheria. This does not prove that the use of serum has lost its value, althoug the reasons for the fact observed are not apparent; the use o serum is today more necessary than ever and confidence in i should not be shaken.

Brunetti spoke of the dangers of intubation in diphtheritic laryngeal stenosis, emphasizing the frequency of chronic laryngeal stenosis in patients in whom the tube is left too long in the larynx. In that manner the air passage is damaged. Research has shown that in such subjects the bronchial tree and the lungs are particularly involved.

Rubatelli spoke on the treatment of chronic postdiphtheritic laryngeal stenosis. This is a therapeutic problem of great importance. The methods that have been tried do not furnish a sure means of preventing grave complications. Stenosis of the respiratory passages is due chiefly to lesions resulting from prolonged intubation.

Radici of Padua described two cases of diphtheritic adenoiditis with dysphagia, in the new-born. He ascribes to the dysphagia symptom great importance in the new-born, owing to the fact that this symptom may, in the absence of visible tonsillar lesions, arouse suspicion of diphtheritic involvement of the pharyngeal tonsil.

Giorgi described a case of diphtheritic polyneuritis in a girl who had never had symptoms of diphtheria but whose sister had diphtheria forty days previously. This patient had been immunized with antidiphtheritic serum. The girl was found to be a carrier of diphtheria bacilli. The speaker held that the antidiphtheritic prophylaxis had caused the diphtheria to remain latent, permitting, however, the production of toxins that caused the paralysis.

In the discussion that followed, Professor Frontali remarked that the laryngologists see more frequently the rare sequels of intubation and of tracheotomy rather than the diphtheritic laryngitis as it actually exists. This leads to differences of opinion. The preference that pediatricians give to intubation, as against tracheotomy, is based on the large proportion (nearly 100 per cent) of cases in which pulmonitis develops in the child following tracheotomy, and on the high mortality (about 50 per cent). Intubation causes a rather low frequency of bronchopulmonary complication and a lower mortality (about 20 per cent). Frontali is of the opinion that the permanent changes in the larynx are due to intubations of long duration. He holds that intubation should not be prolonged beyond 100 hours. Shorter periods of intubation are possible today because serotherapy causes the pseudomembranes to disappear in from twenty-four to seventy-two hours. He said that the Schick test enables one to withhold vaccine treatment in Schick-negative subjects and reveals, after vaccination is done, the persons not yet immune, who can then be given another dose of anatoxin. After any vaccination one may find from 10 to 20 per cent of persons not sufficiently immunized, although Schick negative, who may still be subject to diphtherial infections. He proposed a resolution, which was unanimously approved, in which doubts recently raised against the value of antitoxin and the preventive value of vaccinations with the Ramon anatoxin were stated to be unfounded.

Professor Frontali reported on the treatment of meningitis with a serum produced by the use of the Weichselbaum meningococcus. In the treatment of twenty cases he used specific agglutinant serums directed against types A, B and C of the meningococcus; nine patients received antimeningococcus serum, type B (45 per cent); one, antimeningococcus serum, type C (5 per cent), and ten, antimeningococcus serum, type A (50 per cent). The number of deaths was eight (40 per cent); three patients were improved (15 per cent); nine recovered (45 per cent), and of these only two had any sequels. The results, on the whole, were encouraging. The speaker regretted that the manufacturers of serums in Italy, Switzerland and Germany are unable to furnish specific agglutinant serums for the several types of meningococcus.

Orefice of Vicenza presented the results of his studies on mongolism, calling attention to the increase of this disease, in the last ten years, in the province of Vicenza.

### Meeting of Anatomists

The Società italiana di anatomia held recently, in Palermo, its third annual convention, under the chairmanship of Professor Chiarugi, director of the Istituto di anatomia of the University of Florence. Professor Levi discussed certain changes found in aged persons. He considered the pigment of the nerve cells, the fenestration of the ganglion cells, the decrease in the number of the Purkinje cells, the changes in the caliber of the muscle fibers, the increase of elastic fibers and of the brown pigment of the heart, the increase in the connective tissues and the diminution of the elastic fibers in the vessels, the regression of the lymphatic tissues, the increase of the collagen in the entire organism and of the reticular tissue, with transformation of the latter into ordinary connective tissue.

### Tonsillitis and Kidney Disease

Prof. Camillo Torrigiani, of the University of Florence, delivered recently a lecture on tonsillitis in relation to kidney disease. He discussed various conceptions as to the physiology of the tonsils, pointing out the protective function of the healthy tonsil and the harm that may result from the diseased tonsil. He divided into four types the renal disorders related to tonsillitis: (1) simple albuminuria; (2) focal glomerulonephritis, the most salient characteristic of which is hematuria; (3) diffuse glomerulonephritis, with edema, hypertension, marked albuminuria and sometimes retinitis, and (4) chronic nephritis. Focal glomerulonephritis is the most frequent form. Professor Torrigiani holds that tonsillitis with general symptoms may cause true sepsis but generally is a local infection. He reported 560 cases of tonsillectomy for renal disorders, but he had statistics on the results in only 190 cases. Among these he observed 17 cases of simple albuminuria, 91 cases of acute focal glomerulonephritis, 47 cases of chronic focal glomerulonephritis, and 15 cases of diffuse chronic glomerulonephritis. In 91 cases of an acute focal type, he had 48 recoveries, 23 improvements and 20 cases with a tendency to enter a chronic state. Of the 47 chronic focal types, 25 healed within twelve months, 7 improved and 15 remained unchanged.

### Influenza in Germany

In spite of the hardships that rest heavily on Germany at present, it has not been spared several local epidemics of influenza. The reports based on statistics are not especially disquieting, but every physician knows that, in the past few weeks, we have had to contend with some severe infections. In Breslau, during the last weeks of February and extending over into March, there was an outbreak of influenzal disease, an account of which is given in the *Deutsche medizinische Wochenschrift* by Prof. P. Prausnitz, the director of the Hygienisches Universitäts-Institut in Breslau. He explains the development of the epidemic as due in part to the overcrowding of pupils in the schoolrooms. The recognition of this cause induced the municipal health service to abolish classes or to close schools entirely when at least 10 per cent of the pupils were ill and further overcrowding was contemplated. Thus, on March 11, about 70 per cent of all classes were temporarily disbanded. The rapid retrogression of the epidemic was due, Prausnitz thinks, in no small measure to this procedure. He advanced also the belief that this epidemic, which presented surprising features when compared with earlier epidemics, furnishes evidence of the general lower resistance not only of the pupils but also of adults. Similarly, it could be proved by statistics that the "welfare jobless" furnish more than their proportionate share of the cases, because of the fact that, having been out of work for a long time, they had long since exhausted their savings and their reserves of strength. The Breslau epidemic was of a mild nature, in the main. In Berlin the outbreak did not assume epidemic proportions but in Switzerland there was a conspicuous increase in the morbidity. In England the epidemic appeared with the change of the year. A slight increase of morbidity occurred in Denmark, while in Finland no change was noted. These statements, based on statistics, are of course entirely inadequate for the understanding of epidemic disease that presents such a changing picture as influenza. Everywhere, severe complications and sequels of influenza are found the diagnosis of which is based partly on the clinical course, but chiefly on the leukocyte count, since the bacteriologic manifestations seldom furnish reliable data.

### Diphtheria Carriers

A number of clinicians, writing in the "Kinderärztliche Praxis," emphasize the difficulties of completely eliminating diphtheria bacilli from carriers, for if, as is usually the case, the bacilli are in the throat or nose, they cannot be killed with certainty, and while people are speaking, coughing or sneezing, the bacilli may be easily scattered and become the source of contagion. Professor Husler, in the *Münchener medizinische Wochenschrift*, states that countless attempts have been made to free diphtheria carriers of the bacilli. As a rule, all such attempts fail. The methods employed vary, ranging from gargles of the most diverse kinds, and sprays, to roentgen treatment and even to tonsillectomy. And if one does finally conclude that a sterilization has been brought about, not infrequently the bacilli soon reappear. In view of these facts, it may be just as well to abandon all drastic methods. Simple gargles and, when the bacilli are in the nose, open-air treatment should be used. Many bacillus carriers are harmless, but unfortunately there is no reliable method by which the degree of virulence in man can be tested. Such a test would enable the physician to distinguish between dangerous and harmless carriers. In addition, it is probable that the degree of virulence or infectiousness is not constant. A carrier who has been well for months sometimes may suddenly be taken ill. The isolation of a carrier should not extend over too long a period, as it may impair the development and interfere with the education of the child in question.

### Death of Prof. Carl Spiro

The death of Prof. Carl Spiro, formerly professor of physiologic chemistry at the University of Strasbourg, at the age of 65, is announced. Spiro was a native of Berlin. Near the close of the eighties, he was called to Strasbourg as assistant to the pharmacologist Schmiedeberg, and later to Hofmeister. He retained his professorship up to the time of the dissolution of the German university in 1918, and in 1921 he accepted the chair of physiologic chemistry in Basel. Along with Hofmeister, he was the first to apply physical chemistry to the field of biology and to introduce the colloidochemical mode of thinking into the science of physiology. Spiro was working on a large handbook of colloidochemical medicine when he died. Beyond the limits of his generally recognized scientific performances, Spiro revealed his scholarly nature by aiding at great personal sacrifice his younger colleagues. He shared without stint the treasures gathered by his long experience and studies, and thus advanced the cause of science, while he continued to occupy an obscure position in the background.

### Symposium on Congenital Syphilis

The Royal Medical Society held a debate, January 15, on the present state of our knowledge pertaining to congenital syphilis. Dr. E. Tüdös exhibited a case of syphilis in the third generation. He said, on the basis of cases reported in the literature, that there is no doubt that congenital syphilis may be conveyed to the fetus. The history of the case exhibited by the speaker was as follows: The grandfather acquired syphilis while unmarried. In his marriage, he infected the grandmother. From this marriage, after two abortions, one boy and one girl, both with classic signs of congenital syphilis, were born. The third living prematurely born girl was free from apparent contamination at birth. When 20 years old she married, as an intact virgin. Her husband was perfectly healthy, with a negative Wassermann reaction. In the child born from this marriage, syphilitic osteochondritis of both elbows developed. The spleen was large. The baby had shining soles and enlarged glands at the elbows. The Wassermann reaction was strongly positive. The mother had general adenopathy and she was of a thin, gracile figure; her Wassermann reaction was strongly positive and her teeth were irregular with hutchinsonian changes on the upper central incisors. In this case the assumption of the transference of syphilis to the third generation by the placental route can be regarded as proved.

Prof. J. Guszmann said that, when a daughter is married, syphilitic parents inquire whether syphilis is continued in the offspring; that is to say, in the third generation. In general, it can be stated that the chance is small, as even in absence of treatment the infectivity of the disease disappears in the course of years; therefore, by the time the individual suffering from congenital syphilis reaches the age of 18-20 years, the danger of infection may be regarded as nil. Moreover, the negative possibility of infection is 100 per cent certain if the woman with congenital syphilis is subjected to antisyphilitic treatment during pregnancy. Although the transference is uncommon, it may still occur, as was proved by the family history exhibited by Dr. Tüdös. He had a similar case. The grandmother, now 70 years of age, suffered from acquired syphilis. During her married life she was pregnant, by two husbands, thirteen times. When 48 years of age she presented gummas. At present her Wassermann and Kahn reactions were 4 plus. A daughter of the former suffered from congenital syphilis. Another of her children, the eighth one, when 7 years of age, had his tibia swollen and ulcerated, the process lasting for six years. A 8 years of age the child had a parenchymatous keratitis. Meanwhile gummas occurred in other situations. At present the eburnation of the tibia and its sheathlike curvature, dystrophic teeth and macular cornea can be seen. The Wassermann, Kahn and luetin reactions were 4 plus. The grandchild, the son of the former, 19 years of age, suffers from congenital syphilis. The imbecile boy went to grammar school for three years. In his first two years he had fits. Hearing in his right ear is badly impaired, his speech is muffled and indistinct, and his right eye is cataractous. The palate is strongly arched; he has an asthenic constitution, an idiotic facial expression and microcephalia. The Wassermann, Kahn and luetin reactions are 4 plus.

Professor Sarbó spoke on syphilitic constitution with special regard to familial congenital syphilis. He examined forty-six families, which he divides into three classes: syphilitic parents without tabes or dementia paralytica, and their descendants; tabetic parents; parents with dementia paralytica, and their offspring. In all these classes one can find among the descendants all the manifestations of syphilis; from this he concludes that the individual spirochetes do not evoke different disorders of the nervous system. In other words, the assumption of the existence of neurotropic spirochetes is false. The second problem in conjunction with this topic is: Is it true that in syphilitic marriage the later born children are free from syphilis? He made a thorough investigation and found that this rule is erroneous, as proved by his own cases. Professor Sarbó discussed the question: Is there any and if so what is the difference among the descendants of syphilitic parents as to the possibility of the syphilitic infection? He found, in contrast with data heretofore accepted, that most miscarriages occur among the offspring of parents with dementia paralytica and the fewest miscarriages occur among the descendants of syphilitic parents; on the other hand, in the latter group the number of dead and debilitated fetuses is considerably greater, and the number of healthy children is much greater among the children of parents with dementia paralytica. Heretofore this fact has been explained as due to the attenuation of the virulence of the spirochetes. In opposition to this contention, Professor Sarbó refers to his original conception, on which he published a book some years ago, that patients with congenital syphilis, like those with acquired syphilis, become infected by the blood and lymphatic systems. Cases of juvenile tabes and dementia paralytica are derived from the latter.

As regards the mode of infection, he propounds a new theory. According to him there are individuals whose lymph glands and lymphatic system are so constructed that they prevent the spirochetes in them from getting into the blood system; in such individuals the organism does not get infected through the blood stream and on this account skin manifestations do not appear. This is the reason why they are missing in such cases of congenital syphilis in which tabes and dementia paralytica make their appearance. He supports his assumptions with experimental data and with facts from human pathology. The numerical conditions of the placenta have to be reckoned with. The strikingly great number of healthy descendants of marriages among those with dementia paralytica he ascribes to the fact that in these cases the spirochetes are encased in the lymph glands and therefore the infecting capacity of such patients is considerably less than in those infected through the blood. The prophylactic antisyphilitic treatment of mothers proved to be efficacious in experiences after the war.

Dr. E. Tüdös remarked that the results of Wassermann and other tests give no decisive answer to the question Is congenital syphilis curable? In cases of congenital syphilis, negative Wassermann reactions and freedom from symptoms mean a cure only in a clinical sense. The earlier the treatment is begun, the more probable is complete cure and the elimination of possible late syphilis of the central nervous system.

K. Burger mentioned that many obstetric textbooks state that pregnant women who have had syphilis a long time before need not be subjected to antisyphilitic treatment. This is wrong, he said. Today pregnant women who give a negative Wassermann reaction are treated if, in the history, traces of syphilis appear. The importance of the protection of gravid women is accentuated by every obstetric institute. In many a family latent syphilis is detected by the serologic test made along with the obstetric examination. Antisyphilitic treatment during gravidity is likely to be followed by the delivery of a healthy fetus in from 80 to 90 per cent of the cases.

### Interpretation of Electrocardiograms Taken After Death

Prof. Arthur Hasenfeld exhibited at a recent meeting of the Interhospital Association a series of electrocardiograms proving that electrical phenomena in the heart do not cease completely until thirty-five minutes after the setting in of clinical death. Martini and Schell, who made electrocardiographic examinations, observed electrical phenomena only for nine minutes and thirty-eight seconds after the onset of death. Also the animal experiments of Henrije prove that the electrical phenomena continue after the onset of death. Hasenfeld even succeeded in resuscitating such hearts. His extraordinary observations were made on a woman, aged 62, in his clinic, suffering from severe myocardial degeneration. She died just prior to the electrocardiographic examination. After ineffectual resuscitating experiments lasting for ten minutes, electrocardiographic tests were made at the tenth, twentieth, twenty-sixth, thirty-fifth and forty-fifth minute. In the electrocardiograms, even on the one taken at the forty-fifth minute, the proofs of distorted electrical phenomena were clearly seen. They did not completely cease until forty-five minutes after the onset of death. From his cases Hasenfeld draws the following conclusions: 1. Electrical phenomena may survive death by thirty-five minutes. 2. The possibility of hidden life is undeniable. 3. The resuscitation of the heart is possible; in acute cases (narcosis, intoxication, suffocation) efforts at resuscitation have to be performed energetically for at least half an hour. 4. The contraction of the heart is not the only source of electrical phenomena.

Ankara, April 23, 1932.

### Law Curbs Press on Crime

At the meeting of the mental hygiene society in Istanbul, Prof. Dr. Fahreddin Kerim, the president, made reports on his observations in connection with examinations of feebleminded children made at various outpatient departments; on a project of prohibiting marriage for the mentally afflicted, and the pro and con of their sterilization; on the value of intelligence tests, and on steps the society has undertaken with regard to the establishment of juvenile courts.

According to statistics, in Istanbul in 1928 there were 231 suicides, 116 among males and 115 among females; in 1929 there were 172 suicides, 101 among males and 71 among females; in 1930 there were 86 suicides, 49 among males and 37 among females. All investigation into the causes of these suicides revealed that by far the largest number could be ascribed to extreme poverty, other causes in the order of frequency being nervous breakdown, insanity, alcoholism, love affairs and incurable diseases.

An investigation into the causes of homicides revealed that they were mostly traceable to alcoholism, poverty, unemployment, jealousy, revenge and grudge.

Though suicides have decreased in the last two years, homicides have been increasing, so provisions were made in the law of 1931 to prohibit newspapers or periodicals from publishing photographs or circumstances in connection with suicides, homicides or other crimes in such a manner as to act as an incentive; demoralizing details in connection with divorce cases, or proceedings pertaining to legal medicine if sexual relations are involved; stories either true or fictitious tending to degrade public morals or stimulating the formation of gangs; or articles true or fictitious tending to undermine family life or suggesting that the duties of motherhood are burdensome or otherwise to make motherhood undesirable. From one to two years in prison besides a fine ranging from 200 to 400 Turkish pounds awaits persons violating the respective provisions of the press law; from one week to one year in prison besides a fine of from 25 to 200 Turkish pounds is the punishment for publication of indecent pictures or undesirable pictures in connection with suicides, homicides or other crime.

The mental hygiene society stresses the need of establishing juvenile courts as a means of decreasing crime. As the result of a questionnaire, information was obtained concerning 201 prisons. In December, 1930, the juvenile inmates in 80 prisons numbered 732; in 1931 the average number of juvenile delinquents traceable was 1,310. In only 21 of these 80 prisons are the inmates taught a trade; 26 indicated that they had wards for juveniles and 4 said that juveniles were kept away from adult inmates by the use of special rooms assigned to juveniles only. Five of these eighty prisons have their own physicians; in seventy-five the health officer is called on as the need arises; in five prisons, physical examinations are made at certain intervals, in one once every fortnight, in one every three days, in one every two days, and, in the Istanbul prisons, physical examinations are made every day. The charge of manslaughter was faced by 310 juveniles between the ages of 11 and 20; 200 were involved in robbery and theft, 39 in kidnaping of young women and 27 faced charges of stabbing. In 393 prisons there were 24,000 inmates in 1930, of whom 732 were between the ages of 11 and 20; of these, 231 had both father and mother, 279 had no father, 68 had no mother, and 154 had no father and no mother; 372 juvenile delinquents were born in rural communities and 309 in urban communities; 470 of these juveniles had no schooling at all and 224 discontinued school at an early age; 221 smoked and 20 used alcohol and narcotics; 103 of the juveniles were married between the ages of 14 and 18.

### First Woman Pharmacist

According to the law, the number of pharmacies is limited to one pharmacy to every 10,000 of population. It is therefore becoming more difficult for pharmacists to own a pharmacy and for this reason applications for admission to the school of pharmacology are decreasing. During the last ten years, a number of women have taken up the study of medicine but few take up the study of pharmacology. Having completed the prescribed course at the school of pharmacology and the required practical experience at a pharmacy, Belkis Hanum has been decided on to fill a vacancy that occurred through the death of the proprietor. She thus became the first woman to own and operate a pharmacy.

## Marriages

Morris J. Radin, Hartford, Conn., to Miss Cecile Alta Horowitz of Worcester, Mass., April 10.

Roscoe Rostin White, Logan, W. Va., to Miss Jean Oplinger of Ocean City, N. J., May 21.

William Duncan, Watertown, S. D., to Miss Katherine I. Peabody of Webster, recently.

Morris L. Cable to Miss Raleigh June Gross, both of Minneapolis, in April.

Fuller Albright, Boston, to Miss Claire Birge of New York, May 20.

# Deaths

**William H. De Ford,** Des Moines, Iowa; College of Physicians and Surgeons, Baltimore, 1883; also a dentist; member of the Associated Anesthetists of the United States and Canada; past president of the Iowa State Board of Dental Examiners and the Iowa State Dental Society; formerly professor of pathology, oral hygiene and anesthetics, College of Dentistry, State University of Iowa, professor of dental surgery and anesthetics, Drake University College of Medicine and professor of pathology, anesthetics and exodontia, College of Dentistry, Drake University; aged 73; died, March 22.

**Elmer Hendricks Funk** ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1908; Sutherland M. Prevost professor of therapeutics, materia medica and diagnosis at his alma mater; member of the Association of American Physicians and the American Climatological and Clinical Association; fellow of the American College of Physicians; past president of the Pennsylvania Tuberculosis Association; on the attending medical staff of the Jefferson Medical College Hospital; aged 45; died, May 13, of angina pectoris.

**Roy Bishop Canfield** ⊕ Ann Arbor, Mich.; University of Michigan Medical School, Ann Arbor, 1899; professor of otolaryngology at his alma mater; member of the American Laryngological Association, American Laryngological, Rhinological and Otological Society and the American Otological Society; fellow of the American College of Surgeons; served during the World War; on the staffs of the University and St. Joseph's Mercy hospitals; aged 57; was killed, May 12, in an automobile accident.

**William Webster Root** ⊕ Slaterville, N. Y.; Rush Medical College, Chicago, 1904; founder in 1902, and secretary-treasurer of the Alpha Omega Alpha honorary fraternity; in charge of emergency hospitals and research bacteriologist to Parke, Davis and Company, Detroit, 1908-1911; associate founder in 1925 and secretary-treasurer of the Association of College Honor Societies; for many years on the staff of the Ithaca (N. Y.) Memorial Hospital; aged 64; died, April 23, of arteriosclerosis.

**Francis Hervey Slack** ⊕ Boston; Tufts College Medical School, Boston, 1898; formerly secretary of the city board of health; professor of bacteriology, Kansas State Agricultural College, Manhattan, 1910-1911, and for many years instructor in the biology department, Massachusetts Institute of Technology, Cambridge; formerly on the staff of the Brooks Hospital, Brookline; aged 57; died, May 5, in the Massachusetts General Hospital, of carcinoma and bronchopneumonia.

**Leland Osgood Mauldin** ⊕ Greenville, S. C.; Medical College of the State of South Carolina, Charleston, 1903; member of the American Academy of Ophthalmology and Oto-Laryngology and fellow of the American College of Surgeons; past president of the South Carolina Medical Association and the Greenville County Medical Society; on the staff of the Greenville City Hospital; aged 53; died, May 6, of heart disease, following influenza.

**Albert Montgomery Dupuy McCormick** ⊕ Medical Director, Rear Admiral, U. S. Navy, retired, Berryville, Va.; University of Maryland School of Medicine, Baltimore, 1888; entered the Navy in 1888 and retired in 1930 on attaining the age of 64 years; fellow of the American College of Surgeons; aged 66; died, April 20, in Washington, D. C., of coronary thrombosis.

**William Daniel Hohmann** ⊕ Kewanee, Ill.; Baltimore Medical College, 1890; past president of the Henry County Medical Society; formerly health officer of Kewanee; for many years on the staffs of St. Francis Hospital and the Kewanee Public Hospital; aged 64; died, May 8, of pulmonary and intestinal tuberculosis.

**Lea Wadsworth Tindolph** ⊕ Olean, N. Y.; University of Virginia Department of Medicine, Charlottesville, 1906; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staff of the Olean General Hospital; aged 59; died, April 25, of acute dilatation of the heart and lobar pneumonia.

**Thomas Wotton Bickerton** ⊕ Fanwood, N. J.; College of Physicians and Surgeons in the City of New York, 1881; member of the Medical Society of the State of New York; for twenty years medical director of the New York Life Insurance Company; aged 78; died, May 4, of heart disease.

**George Donohoe** ⊕ Cherokee, Iowa; Harvard University Medical School, Boston, 1898; member of the American Psychiatric Association; medical superintendent of the Cherokee State Hospital; aged 56; died, May 13, in Rochester, Minn., following an operation for ulcers of the stomach.

**Julius Elwood Hiatt** ⊕ Richmond, Ind.; University of Indianapolis Medical Department, 1902; past president of the Wayne-Union County Medical Society; formerly coroner of Henry County; on the staff of the Reid Memorial Hospital; aged 62; died, April 1, of cerebral hemorrhage.

**Charles William Chastain,** Plattsburg, Mo.; University of Missouri School of Medicine, Columbia, 1880; College of Physicians and Surgeons in the City of New York, 1881; for many years member of the school board; deputy state health commissioner; aged 74; died, April 19.

**Lee Preston Somers,** New Castle, N. C. (licensed, North Carolina, 1889); member of the Medical Society of the State of North Carolina; aged 67; died, April 16, in the Davis Hospital, Statesville, of carcinoma of the colon, stomach and liver and chronic interstitial nephritis.

**John R. Minehart** ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1903; professor of pharmacognosy and bacteriology and dean of the school of pharmacy, Temple University; aged 53; died, May 10, in the Temple University Hospital, of cerebral hemorrhage.

**Adolph J. Girardot,** Toledo, Ohio; Detroit College of Medicine, 1895; served during the World War; formerly on the staff of St. Vincent's Hospital; aged 61; died, April 15, in the Veterans' Administration Hospital, North Chicago, of chronic pulmonary tuberculosis.

**Frank Blair Humphreys** ⊕ Angola, Ind.; University of Michigan Medical School, Ann Arbor, 1892; served during the World War; formerly county coroner, and member of the school board of Angola; aged 66; died, May 10, of influenza and pneumonia.

**John Emory Reed,** Benton, Ill.; St. Louis College of Physicians and Surgeons, 1910; member of the Illinois State Medical Society; served during the World War; division superintendent of public health; aged 51; died, April 25, of heart disease.

**Thomas A. D. Baird** ⊕ Bay City, Mich.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1885; aged 69; on the staffs of the Bay City General Hospital and the Mercy Hospital, where he died, April 27, of lobar pneumonia.

**Franklin Edward Williams,** Vienna, Ga.; University of Georgia Medical Department, Augusta, 1902; member of the Medical Association of Georgia; aged 50; died, April 25, in the Oglethorpe Private Infirmary, Macon, of heart disease.

**William Blake,** Detroit; Faculty of Medicine of Trinity College, Toronto, Ont., Canada, 1873; member of the Michigan State Medical Society; formerly mayor of Lapeer, Mich.; aged 87; died, May 2, of arteriosclerosis and gangrene.

**Robert Frank Flowe,** Kannapolis, N. C.; North Carolina Medical College, Charlotte, 1913; member of the Medical Society of the State of North Carolina; aged 43; died, April 30, in the Jefferson Hospital, Philadelphia, of empyema.

**James Francis O'Leary,** Shreveport, La.; Bellevue Hospital Medical College, New York, 1873; member of the Louisiana State Medical Society; Confederate veteran; aged 85; died, April 19, of bronchopneumonia and influenza.

**George Thomas Boyd** ⊕ Los Angeles; Kansas City Medical College, 1905; served during the World War; aged 58; on the staff of the Hollywood Hospital, where he died, May 5, of an overdose of drugs, self-administered.

**Oliver H. Paxson,** Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1890; emeritus professor of therapeutics at his alma mater; served during the World War; aged 72; died, May 9, of heart disease.

## CARRIERS OF HEMOPHILIA

*To the Editor:*—I read with interest the inquiry as to whether or not female hemophilia carriers could be detected by any method, and your reply thereto, which appeared in The Journal, May 7, page 1679. It has always been my opinion that none of the tests proposed are of any value, whereas in your reply you take the stand that although the tests are not absolutely reliable, when positive they would constitute strong evidence that the woman in question was a carrier.

May I quote the following, which appeared in *Eugenical News,* December, 1931, page 214:

> There seems to be considerable popular misapprehension concerning the possibility of determining a female carrier of hemophilia by some blood or chemical test, whereas as far as medical science now knows, the only method differentiating between a woman, from an affected family who is a carrier of hemophilia, and one from the same family who is not a carrier, is to let each produce sons or grandsons and to determine the proportion of hemophiliacs among them. . . . Dr. Carroll L. Birch states on November 23 in a letter to *Eugenical News:* "In recent years two proposed tests have appeared in the literature; one concerned the type of the blood, and the other the reaction of the blood to cobra venom. Neither of these tests have proven successful."

With special reference to the relationship between blood groups and hemophilia, I said in a paper (*Genetics,* May, 1932, p. 336):

> Kubanyi has determined the blood groups of members of hemophiliac families, in order to determine the presence or absence of linkage. Kubanyi's work, it would seem, is unnecessary, for hemophilia is a sex-linked trait, whereas blood groups are not, so that linkage between these two characters is hardly possible.

As a matter of fact, a careful analysis of Kubanyi's data will show no evidence of linkage between blood groups and hemophilia. Perhaps some ambitious worker will now try to determine whether or not the recently discovered agglutinogens M and N of Landsteiner and Levine are linked to hemophilia. Such work also would be futile, however, since the agglutinogens M and N are not sex linked.

Alexander S. Wiener, M.D., Brooklyn.

## "ALLERGIC INERTIA AND AVITAMINOSIS"

*To the Editor:*—I am much interested in the editorial in The Journal, April 23, entitled "Allergic Inertia Due to Avitaminosis." The editorial quotes the work of Hurwitz and Wessels purporting to show that there is a lack of parallelism between the reactivity of the bronchial smooth musculature and the uterine musculature. The authors are quoted as indicating that, in a controlled series of experiments, they found this disparity due probably to a vitamin deficiency.

In a study that I made in association with H. L. Gruehl, reported in the *Proceedings of the Society for Experimental Biology and Medicine* (**26**:197, 1928) and published in extenso in the *Journal of Laboratory and Clinical Medicine* (**16**:1069 [Aug.] 1931), we compared the anaphylactic response of a sensitized animal to various routes of shock demonstration, and in comparing the Schultz-Dale method with the intravenous we showed in a series of twenty-three animals that in eleven animals there was a similar response of the uterine strip and the bronchial musculature, in one animal there was a doubtful reaction of the uterine muscle with a positive bronchial constriction, in six animals there was negative uterine constriction and positive bronchial constriction, and in five animals both were negative.

Our series of animals is similar to that quoted by Hurwitz and Wessels, and it will be noted that our animals were all fed alike. They all received green leafy vegetables which are sent regularly from a neighborhood vegetable market. We believe, therefore, that the vitamin content of their diet was in no way different. Our conclusions in this study were merely to the effect that smooth muscles are not all sensitized to an equal degree, and that the muscles in the guinea-pig that respond most regularly to anaphylactic sensitization are the smooth muscles of the bronchioles, and further that the most regular results of anaphylactic shock in the guinea-pig are brought about by the intravenous route.

In another experiment (*Proc. Soc. Exper. Biol. & Med.* **26**:127, 1928) we sensitized virgin guinea-pigs by inhalation and showed that the inhaled substances sensitized the bronchial musculature, and in certain instances also sensitized the uterine musculature.

In view of the work quoted, we can merely indicate that at times the musculature of the uterus does not become sensitized. Again we cannot attribute this to avitaminosis. It appears to me that in the domain of anaphylaxis and allergy there are many conclusions drawn that are not warranted, and that there is not enough understanding of the irregularities that exist in sensitization. There must be many factors that play a rôle. Possibly vitamin deficiency does, but I do not believe that the paper of Hurwitz and Wessels has demonstrated this.

Bret Ratner, M.D., New York.

# *Queries and Minor Notes*

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

## ALLERGIC RHINITIS

*To the Editor:*—For the past five years my wife has had daily attacks of what I first thought was a hyperesthetic rhinitis. The attack usually was ushered in by a complete occlusion of both nares and a sensation as though the pressure within was about to burst the nose. Then profuse rhinorrhea would take place, as well as a period of sneezing. One nose and throat man, who said that a small spur on the septum was responsible, did a submucous resection, but the condition was aggravated. Then one inferior turbinate was cauterized, with slight relief. Allergic tests were negative. The frontal sinuses are normal. Seven teeth presumably causing a focal infection were extracted. She went to Texas because of a more equable climate; slight relief was obtained but still the attacks persisted. At present she has an attack at about 4 or 5 a. m. and is awakened because of the inability to breathe through the nostrils. After assuming the upright posture, she obtains some relief and soon starts to sneeze and has a profuse discharge of a watery secretion. She is 39 years of age and was always in excellent health until this trouble started. Urinalysis, blood examination and basal metabolism determination show nothing. Will you please give me any information as to the etiology and treatment of such a case? M.D., Illinois.

Answer.—The symptoms—occlusion of the nares, feeling of pressure, rhinorrhea and sneezing—are characteristic of allergic rhinitis, also called hyperesthetic or vasomotor rhinitis, or perennial hay fever. The fact that two nasal surgical procedures were carried out with no relief confirms the diagnosis of an allergic condition; i. e., hypersensitivity to something probably containing protein. The rest is detective work. Skin tests are of the greatest help and should be done thoroughly. It is not sufficient to do a dozen or twenty. Such testing is incomplete and only casts reflection on the allergic management of these cases. The patient should be tested for all sorts of epidermals, for every food she eats, for pollens, and for miscellaneous substances like orris root and pyrethrum (insecticides). Scratch tests are probably best and, if negative, should be followed up by intradermal tests. By this thorough examination there is much more chance of locating the offending material than by incomplete and haphazard testing. After these tests have been carried out and if negative again, certain other management is indicated. The history of the time of the attacks strongly suggests that the irritating substance is in the bedroom. Therefore rugs should be removed, and the draperies or curtains should be thoroughly cleaned, along with the rest of the room; a good vacuum cleaner is best here. The pillows and mattress should be encased in light rubber sheeting and sewed with triple stitching so that there is no possibility of particles of feathers or cotton or horsehair escaping. If all these measures fail to bring relief, attention must be directed elsewhere. All animals should be removed from the house; face powder should be free from orris root or not used at all; talcum powder and bath powders must be avoided. If all these procedures are likewise unsuccessful, attention to the diet may help. Autogenous vaccine from the nasal secretion may be of aid.

### ERYTHEMA NODOSUM

*To the Editor:*—A white woman, aged 40, had an acute membranous sore throat and tonsillitis with typical symptoms six weeks ago. This cleared up quite readily with a 10 per cent solution of mild silver protein and acetylsalicylic acid. Seven days later an inflamed, indurated, tender area appeared just distal and somewhat lateral to the left patella, free of the tibia. This area was slightly raised, quite hot, with color disappearing on pressure, and there was no fluctuation. Within the next week there were many more similar areas on the left leg as well as on the right, another below the left elbow posterior aspect and an area of conjunctivitis on the nasal side of the right eye. There never was evidence of pathologic change in any internal organ. The patient never looked or felt severely ill, felt weak and had considerable pain in walking. These lesions have steadily improved in the past four weeks, but when the patient stands they become a bluish hue, which worries her, together with her extreme weakness. To my mind there must have been a bacteremia present with multiple areas where they became lodged in the blood stream. Is this diagnosis correct and what would be the correct manner of treatment? The temperature since the development of the lesions has ranged from normal to 100 F. Please omit name.

M.D., Nebraska.

Answer.—The condition described, including onset with a history of sore throat, followed by inflamed, tender lesions, chiefly on the lower limbs, corresponds to that of erythema nodosum. The course is usually mild and the fever is slight. Several weeks is often required for the disappearance of the lesions, and there may be recurrences. The condition frequently begins with sore throat or pharyngitis, which, with the fever and other symptoms, suggests an acute infectious disease. There are usually no sequelae. Movement of the extremities may be painful on account of the local tender nodes.

In some years there occur a number of cases in one locality, while in other years only an occasional isolated case is encountered.

The appearance of the lesions strongly suggests an embolic lodgment of organisms, occurring during the course of a bacteremia. In one series of cases routine blood cultures yielded in two instances colonies of small nonhemolytic streptococci, while in several other cases blood cultures showed no growth.

In treatment during the acute illness, sodium salicylate or some other salicyl compound gives relief from pain. Rest in bed, or at least relative rest, is desirable.

Weakness, lassitude and anemia are noted following the disease, as in acute rheumatism, and call for iron therapy and other supportive treatment.

### KAHN TEST AND WASSERMANN

*To the Editor:*—Will you kindly advise whether the acetone insoluble test is more delicate and more definite than is the Kahn test in determining a Wassermann reaction?

J. H. Turner, M.D., Huntington Park, Calif.

Answer.—It is assumed that by "the acetone insoluble test" is meant the Wassermann test in which is employed an acetone insoluble antigen. This antigen was perfected by Noguchi, who believed that the acetone insoluble fraction of heart tissue lipoids was superior as a Wassermann antigen to the acetone soluble fraction. The use of acetone insoluble antigen in the Wassermann test was in considerable vogue two decades ago. Its use has gradually been abandoned, owing largely to its insufficient sensitivity. The Kahn test is generally considered more sensitive than the Wassermann test with an acetone insoluble antigen. Caffey and Kreidel (*Am. J. Dis. Child.* 38:1206 [Dec.] 1929), who made a comparative study of the two tests, reported the Kahn to be more sensitive and more specific.

### PREGNANCY AFTER CHILDBIRTH WITHOUT INTERVENING MENSTRUATION

*To the Editor:*—Can pregnancy occur following a prior childbirth without an intervening menstruation? The question is asked in the interest of a multipara, aged 32, whose youngest baby is now 7 months old. She nursed the baby for three months and has not menstruated since the beginning of pregnancy sixteen months ago. She now presents the classic symptoms of a three months' gestation. Can a virgin become pregnant prior to the first menstruation?

Willis P. Baker, M.D., Santa Ana, Calif.

Answer.—Pregnancy can and does often occur after childbirth without an intervening menstruation. There is a common belief among the public that a woman who nurses a baby cannot conceive as long as lactation continues and for this reason many women do not use contraceptives during this period. This belief is erroneous, as is the notion that a woman does not menstruate while she is nursing a baby. Women may become pregnant even within a few weeks after delivery. In one case no menstruation occurred for a period of eight years because of constantly repeated pregnancies. A virgin can become pregnant before the onset of the first menstruation. Likewise gestation is possible after the menopause has occurred. From the foregoing it may be seen that even though menstruation may be absent during such physiologic periods as childhood, lactation and the change of life, ovulation may nevertheless occur and conception is possible. Even during pregnancy in some instances ovulation may occur and this is the basis for the belief that superfetation may take place.

### SEX DESIRE AND MENOPAUSE—HIGH VOLTAGE ROENTGEN THERAPY IN CANCER

*To the Editor:*—In regard to the artificial induction of the menopause in women by means of the x-rays, I should like to ask whether sexual frigidity is a common consequence. What percentage of frigidity accompanies or follows the normal menopause? In cancer of the uterus does irradiation with 200,000 volts or higher possess definite, proved curative results that cannot as well be obtained by the 140,000 to 160,000 volt technic? Please omit name.

M.D., California.

Answer.—Gradual loss of sexual desire may be a sequence of the artificial menopause. Maintenance of sex desire appears to be slightly more common than after the normal menopause. As a rule, lack of sex desire accompanies the normal menopause, although a considerable number of women continue to be sexually active for some years. A 200,000 volt machine furnishes the minimum amount of energy for satisfactory high voltage roentgen therapy. A still stronger voltage is preferable.

### MENSTRUAL CYCLE

*To the Editor:*—In Queries and Minor Notes, March 19, appeared an answer to a question on "Physiologic Sterility and Conceptive Capacity," in which mention was made of experimental work being done along this line by Knaus and a combination of disks worked out by him. Where may one obtain these conclusions arrived at by Knaus, as well as the disks? In mentioning the "menstrual cycle," where does one begin? In other words, which is the first day of the cycle? Please omit name and city.

M.D., Iowa.

Answer.—The articles by Knaus are written in German, but abstracts of these papers may be found in the 1929 Year Book of Obstetrics and Gynecology by J. B. De Lee and J. P. Greenhill, pages 21-22, and in the 1931 Year Book, pages 363-364. In the latter article are comments by Greenhill on the matter of physiologic periods of sterility in women. The most recent original articles are:

Ueber den Zeitpunkt der Konzeptionsfähigkeit des Weibes, *Arch. f. Gynäk.* **146:** 343, 1931.
Sterilizierung und Konzeptionsverhütung, *Zentralbl. f. Gynäk.* **55:** 2854, 1931.

The disks may be obtained by writing to Konzip-Hauptvertrieb, Stübing bei Graz, Austria.

By the beginning of the menstrual cycle, the day the menstrual bleeding begins is meant. This is the first day of the cycle.

### GOITROGENIC PROPERTIES OF CABBAGE

*To the Editor:*—1. Why do experimental animals fed on cabbage develop goiter? 2. Is it the result only of an exclusive cabbage diet? 3. Is the goiter in question simple, colloid or hyperplastic? 4. What bearing on the diet of man has a liberal amount of raw or cooked cabbage?

L. W. Meckstroth, M.D., Chicago.

Answer.—1. Because of the presence in cabbage of a goitrogenic substance. This goitrogenic property is, in general, inversely proportional to its ability to absorb iodine (Marine and others).

2. No. Cracker dust (Hunt), fat to pigeons (McCarrison), liver to dog, fowl or trout (Marine and Lenhart) will also produce goiter. Brussel sprouts and cauliflower have about the same potency as cabbage. The goitrogenic property is greatly increased by steaming.

3. Hyperplastic.

4. Cooking or steaming the cabbage greatly increases its potency in producing hyperplasia. Hashed fresh cabbage has little property of producing thyroid hyperplasia. In most of this work on rabbits, cabbage was the principal food of these animals. It seems doubtful whether enough cooked cabbage would be ingested daily by a given individual over a long enough period to produce a hyperplastic thyroid gland.

The following references are pertinent:

### POISONING BY ERGOAPIOL

*To the Editor:*—Will you please send me the formula of ergoapiol, manufactured by Martin H. Smith Company, New York. I would also appreciate if you send me any reports of poisoning or deaths due to the use of this drug if they have been reported in the medical literature. A patient of mine died in the hospital today and the postmortem revealed a severe toxic, fatty metamorphosis in the liver and kidneys and heart. She gives a history of having taken eighteen ergoapiol capsules within forty-eight hours in order to induce an abortion, together with self-insertion of a rubber tip into the uterus. Following this she began to bleed and passed clots, the bleeding ceasing in three days. The next day she began to vomit and had diarrheal movements. The next day she became jaundiced and was unable to urinate and in the succeeding eight days passed only 16 ounces of urine in spite of all measures to induce diuresis. During her entire illness she had a normal pulse and temperature. I believe she was chemically poisoned by the ergoapiol, although we were unable to have a toxicologic examination of the kidneys or liver. I understand that this preparation can be purchased by the public in drug stores without a doctor's prescription, and I believe that measures should be taken to prevent this in view of the toxic nature of the preparation.

J. J. Labow, M.D., Elizabeth, N. J.

Answer.—The symptoms and the tragic ending in the case reported are quite evidently due to volatile oil poisoning, such as occurs unfortunately too commonly from the use of these oils as abortifacients. The formula for Ergoapiol given by the manufacturers is:

| | |
|---|---|
| Apiol (Special) | 5 grains |
| Ergotin | 1 grain |
| Oil Savin | ½ grain |
| Aloin | ⅛ grain |

The "Apiol" in this preparation is very probably the oleoresin of parsley seed. The dose taken by the patient of either this oleoresin or of the oil of savin, and still more especially of the two combined, would be adequate to produce the gastro-enteritis, hepatitis and nephritis, which might be postulated as having been produced, on the basis of the symptoms observed.

### PARALYSIS OF VOCAL CORDS

*To the Editor*—I have a patient who developed a paralysis of the left vocal cord following an abdominal operation, a complication which seems most remote. Physostigmine, however, was given for abdominal distention, and the paralysis was peripheral in origin. Is physostigmine known to have any special action on the vocal cords? If so, does it do permanent damage? Please omit name.

M.D., Long Island.

Answer.—Physostigmine (eserine) stimulates many involuntary muscles in the body. We do not know that any effect has ever been noted on the vocal cords. The paralysis of the left vocal cord must have been due to some other coincidence or lesion. Whether the effect on the vocal cord will be permanent or not depends on the type of injury to the recurrent laryngeal nerve, and its nature cannot be determined without knowing what other factors may have been present besides the use of physostigmine.

### EDEMA OF FOOT AFTER INJURY

*To the Editor:*—Perhaps you will be able to assist me with this problem. I have a man under my care, aged 30, who was injured in November, 1931. His foot and leg were caught between two heavy iron rollers of a conveyor. The rollers were about 2 inches apart, but there was some give to them, so that they could be spread farther apart with force. A roentgenogram showed no dislocations or fractures, and none could be demonstrated clinically. There was a great amount of pain and swelling in the foot and leg immediately following the accident. The foot and lower part of the leg were placed in a circular plaster cast for three weeks, which relieved the pain. After removal of the cast there was still marked edema of the foot and leg up to the point at which the rollers were stopped. He was allowed up on crutches. Gradually the edema in the leg disappeared, but it still persists in the foot, especially just above the toes. There is moderate pain on pressure over the edematous parts, and also on pressure on the sole beneath the long arch The foot feels better when supported with a Gibney boot of adhesive tape, but there never is any severe pain, except when weight is borne on it. There is no limitation of motion in the ankle joint, and neither voluntary nor passive motion of this joint, or the joints of the toes, gives any pain. The treatment has consisted of support with adhesive tape, as that seems to make it feel the best. For three weeks the support was left off and the patient was advised to soak the foot in strong epsom salt solution, but no improvement resulted. Another roentgenogram was taken three weeks ago and no pathologic signs were found by the chief of the x-ray department. Any advice or assistance you can give to me as to diagnosis or treatment will be appreciated.

Louis LeFevre, M.D., Muskegon, Mich.

Answer.—A proper round-toe shoe with a rigid shank should be worn. In the shoe a felt or rubber pad should be inserted to support the longitudinal arch. If there is valgus deformity of the foot, the inner border of the heel should be built up three-sixteenths inch.

The foot should be massaged twice daily, any type of anodyne ointment being used.

Contrast sprays should be used, the patient sitting in the tub and spraying with warm and cool water alternately for ten minutes.

An elastic anklet may be of value, to be worn part of each day.

Exercises for the longitudinal and transverse arches should be started as soon as possible.

### INTERMENSTRUAL PAIN, OR "MITTELSCHMERZ"

*To the Editor:*—A married woman, aged 31, complains of cramps in the lower abdominal region two weeks after her menstrual period. They are severe enough for her to go to bed. She also has some pains during the menses, which come every twenty-eight days. Her mother states that she had the same trouble until after she passed the menopause period. What can account for this kind of pain and what line of treatment should be followed? Would cystic ovaries cause such symptoms? Another patient complains of severe epigastric pains periodically every six weeks. She has been to several doctors but none seemed to give her much relief. The pains stay with her from five to seven days and then disappear, leaving her entirely well. Blood, urine and genital examination prove negative. Gastric examination showed only diminished free hydrochloric acid. *Otherwise the patient is the picture of health.* What possible causes may account for it? Please omit name.

M.D., Nebraska.

Answer.—Intermenstrual cramps, occurring approximately two weeks before the flow, are usually caused by bursting of the ovary incident to extrusion of the ovum. This symptom, called "intermenstrual pain," or "mittelschmerz," often arises from only one ovary and may occur only every second month or even less frequently. It affects, particularly, rather delicate patients, although occasionally those of robust constitution and placid nerves have considerable distress. The duration of the pain may be only a few minutes, but the majority experience some discomfort for several hours. Rest in bed and a hot water bag usually suffice; codeine may be given without hesitancy.

Although the periodic attacks of epigastric pain complained of by the other patient suggest a possible relationship to the genitalia, the high location of the discomfort speaks against a genital focus. Modern gynecologists have little faith in "reflex" symptoms due to genital lesions. Lesions of the intestine occasionally produce symptoms only at the time of pelvic congestion incident to menstruation. For example, chronic appendicitis may cause no distress except at this time.

### STARCH AS ANTIDOTE IN IODINE POISONING

*To the Editor:*—In the twentieth edition of the U. S. Dispensatory on page 593, it states that "in the case of iodine poisoning the stomach must be evacuated and drinks administered, containing an amylaceous substance." Is there any difference in the administration of raw starch and boiled starch as an antidote for iodine and is it considered advisable to evacuate the stomach before giving the antidote? M.D., New Jersey.

Answer.—Boiled starch would constitute the more efficient antidote, because it combines much more actively with iodine than raw starch. Nevertheless, in an emergency, no time should be lost in administration of the antidote and the raw used if procuring of boiled starch would delay administration. For the same reason, the starch should be administered even before the passing of the stomach tube.

### SECONDARY PNEUMOCOCCUS PERITONITIS

*To the Editor:*—A child, aged 2½ years, developed pneumonia with diffuse general pneumococcus peritonitis as a complication. This was proved by inserting a needle and withdrawing and examining the fluid. Should the child be operated on or left alone? What is the prognosis either way? Kindly omit name.

M.D., New York.

Answer.—Secondary pneumococcus peritonitis as indicated in this case is reported to be slightly less fatal than the primary form. In a review of fifty-six cases in children, McCartney and Fraser (*Brit. J. Surg.* 9:479 [April] 1921) concluded that early operation was indicated in all cases of pneumococcus peritonitis. This should be done under gas and oxygen, or with local anesthesia. These authors found that the mortality in their series of cases before early operation was instituted averaged 65 per cent; after earlier recognition with immediate operation, the mortality rate dropped to 53 per cent. Later they added blood transfusion, which they insisted must be done at the onset of the period of septicemia to give the best results. Their mortality rate then dropped to 42 per cent.

Many patients die within one or more days regardless of the treatment. Any localized abscess should be drained at that point. Since many of the cases, especially the primary ones in the female, are believed to arise from the pneumococcus gaining entrance through the fallopian tubes, the pelvis is the chief site of the peritonitis and the abdomen should be drained as low as possible. Vaginal drainage has proved satisfactory in the diffuse primary type of peritonitis in children.

In addition to early operation and blood transfusion when indicated, fluids should be given through the skin, so that the gastro-intestinal tract is permitted absolute rest.

### DETERMINATION OF HEMOGLOBIN

*To the Editor:*—Can you tell me approximately what the relative accuracy is between the determination made on a Bausch and Lomb "Newcomer hemoglobinometer" and the "hemoglobin outfit" manufactured by the LaMotte Chemical Products Company of Baltimore? As I wish to use this apparatus for clinical work, a small percentage of error is of no great consequence, but I would want a method that is more accurate than the ones commonly used in office practice.

George H. Clark, M.D., Oskaloosa, Iowa.

Answer.—The actual quantitative determination of hemoglobin has been a subject of much discussion during recent years. Articles have appeared from time to time comparing the methods in current use and calling attention to sources of error. These have been followed by modifications that have increased the accuracy of the determinination. This has been particularly true of the Sahli and the Newcomer instruments. The LaMotte hemoglobin outfit is the most recent and embodies a modification of the original Wong method, which determined hemoglobin through its iron content. The results are reported in the number of grams of hemoglobin per hundred cubic centimeters of blood. The latest model of the Bausch and Lomb Newcomer hemoglobinometer also uses the quantitative reading instead of employing a percentage based on an arbitrary standard of what constitutes 100 per cent. In view of our lack of modern data of what 100 per cent represents, it is advisable to determine hemoglobin in grams per hundred cubic centimeters directly. While no recent studies are available on the comparison of the relative accuracy of the latest instruments, there is reason to believe that the ones mentioned are satisfactory for most purposes, as they have been carefully checked against more accurate methods.

### POSSIBLE OPTIC ATROPHY FROM CIGARETS IMPREGNATED WITH TOILET WATER

*To the Editor:*—I have a patient with partial optic atrophy who for the past six or eight months has smoked cigarets impregnated with toilet water. He estimates that during this time he has used 5 or 6 ounces of the toilet water. He first noticed failing vision about two months after he smoked these cigarets. He has been a moderate drinker for years but so far as he knows the whisky he has drunk has *not been* adulterated. The toilet water probably contains wood alcohol. Is it possible that smoking cigarets containing it could produce optic atrophy? I should think that when lighted the alcohol would evaporate, but possibly a poisonous residue might be left. Any information you can give me on the subject will be appreciated.

Grace Tankersley, M.D., Pine Bluff, Ark.

Answer.—It is possible that smoking cigarets that have been saturated with toilet water could cause optic atrophy. As suggested, there is undoubtedly methyl alcohol in the toilet water and liquid or, rather, unevaporated methyl alcohol may remain in the tobacco, even after considerable drying has occurred. When the cigaret is ignited, the fumes of the alcohol (which has a low boiling point of 66 C.) will be carried in with the tobacco smoke and absorbed from the mucous membranes. As only a small amount would be inhaled from each cigaret, not enough poisons would be absorbed to cause the symptoms of an acute methyl alcohol poisoning; but there would be sufficient to produce the almost specific damage to the optic nerve fibers, provided the individual was of the susceptible type. The susceptibility to damage from the small amounts of methyl alcohol was undoubtedly increased by the tobacco fumes as well as the ethyl alcohol and fusel oils of the accessory whisky.

### ANASTOMOSIS OF FALLOPIAN TUBES

*To the Editor:*—Can anastomosis of tubes resected and tied seven years ago be reestablished by operation? The patient is 28, had had no pelvic inflammatory disease, and had five pregnancies prior to the sterilization operation.

Willis P. Baker, M.D., Santa Ana, Calif.

Answer.—The outlook for relief of sterility in patients with tubal obstruction limited to the fimbriated extremity is excellent. Tubal resection, transplantation of the resected tubes into the uterus, or laying open the obstructed distal portions of the tubes usually results in failure. Theoretically, it should be possible to anastomose tubes which have been resected, but experience indicates that the prognosis is unfavorable in cases such as the one in question.

# Council on Medical Education and Hospitals

## COMING EXAMINATIONS

Alabama: Montgomery, July 11. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

American Board for Ophthalmic Examinations: Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

Arizona: Phoenix, July 5-6. Sec., Dr. B. M. Berger, 12 North Central Ave., Phoenix.

California: *Reciprocity.* Los Angeles and San Francisco, June 15. *Regular.* San Francisco, July 11-14. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

Colorado: Denver, July 5. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

Connecticut: *Basic Science.* New Haven, June 11. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven. *Regular.* Hartford, July 12-13. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic.* New Haven, July 12. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

Delaware: Wilmington, June 14-16. Sec., Dr. Harold L. Springer, 1013 Washington St., Wilmington.

District of Columbia: *Basic Science.* Washington, June 29-30. *Regular.* Washington, July 11-12. Sec., Dr. W. C. Fowler, 203 District Bldg., Washington.

Florida: Tampa, June 13-14. Sec., Dr. W. M. Rowlett, 812 Citizens Bank Bldg., Tampa.

Georgia: Atlanta, June 15-16. Joint Sec., Mr. R. C. Coleman, 111 State Capitol Bldg., Atlanta.

Hawaii: Honolulu, July 11-14. Sec., Dr. James A. Morgan, Room 48, Young Bldg., Honolulu.

Illinois: Chicago, June 28-July 1. Supt., Mr. Paul B. Johnson, Springfield.

Indiana: Indianapolis, June 21-23. Sec., Dr. William R. Davidson, 413 State House, Indianapolis.

Kansas: Kansas City, June 21-22. Sec., Dr. C. H. Ewing, Larned.

Louisiana: New Orleans, June 9-11. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

Maine: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, Jr., 192 State St., Portland.

Maryland: *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore. *Regular.* Baltimore, June 21-24. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore.

Massachusetts: Boston, July 12-14. Sec., Dr. Stephen Rushmore, 144 State House, Boston.

Minnesota: Minneapolis, June 21-23. Sec., Dr. E J. Engberg, 524 Lowry Medical Arts Bldg., St. Paul.

Missouri: St. Louis, June 14-16. Sec., Dr. James Stewart, Capitol Bldg., Jefferson City.

National Board of Medical Examiners: Examinations in Parts I and II will be held at all centers where there are five or more candidates, but *not* at Durham, Minneapolis, nor New Haven, June 27-29. Ex. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia.

Nebraska: *Regular.* Omaha, June 9-11. Dir., Mrs. Clark Perkins, Lincoln.

New Jersey: Trenton, June 21-22. Sec., Dr. James J. McGuire, 1101 Trenton Trust Bldg., Trenton.

New York: Albany, Buffalo, New York, Syracuse, June 27-30. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315, State Education Bldg., Albany.

North Carolina: Raleigh, June 20. Sec., Dr. John W. MacConnell, Davidson.

North Dakota: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, Grand Forks.

Oregon: Portland, July 5-7. Sec., Dr. C. J. McCusker, 1014 Medical Dental Bldg., Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 5-9. Sec, Mr. Charles D. Koch, Dept. of Public Instruction, Harrisburg.

Rhode Island: Providence, July 7-8. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

South Carolina: Columbia, June 28. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

South Dakota: Waubay, July 19. Dir., Dr. H. R. Kenaston, Bonesteel.

Texas: Marlin, June 21-23. Sec., Dr. T. J. Crowe, 918-19 Mercantile Bank Bldg., Dallas.

Utah: Salt Lake City, July 6-8. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

Vermont: Burlington, June 22-24. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 15-18. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

Washington: *Basic Science.* Seattle, July 7-8. *Regular.* Seattle, July 11-12. Dir., Mr. Charles Maybury, Olympia.

West Virginia: Harpers Ferry, July 12. Sec., Dr. W. T. Henshaw, State Health Dept., Charleston.

Wisconsin: Milwaukee, June 28-30. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

## Wyoming February Report

Dr. W. H. Hassed, secretary, Wyoming State Board of Medical Examiners, reports 2 physicians licensed by reciprocity with other states, Feb. 15, 1932. The following colleges were represented:

| College | LICENSED BY RECIPROCITY | Year Grad. | *Reciprocity* with |
|---|---|---|---|
| Creighton University School of Medicine | | (1928) | Nebraska |
| University of Wisconsin Medical School | | (1929) | Utah |

### Vermont February Report

Dr. W. Scott Nay, Vermont State Board of Medical Registration, reports the written examination held at Burlington, Feb. 9-11, 1932. The examination covered 12 subjects and included 90 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Two physicians were licensed by endorsement, Jan. 1 and March 15, 1932, respectively. The following colleges were represented:

| College | PASSED | Year Grad. | Per Cent |
|---|---|---|---|
| University of Pennsylvania School of Medicine | | (1930) | 90 1 |
| University of Vienna Faculty of Medicine | | (1919)* | 84.5 |
| University of the Dominican Republic Faculty of Medicine and Natural Sciences | | (1910) | 85 |

| College | LICENSED BY ENDORSEMENT | Year Grad. | Endorsement of |
|---|---|---|---|
| University of Edinburgh Faculty of Medicine | | (1925) | N. B. M. Ex. |
| Yale University School of Medicine | | (1910) | Mass. |

* Verification of graduation in process.

### Maine March Report

Dr. Adam P. Leighton, Jr., secretary, Maine Board of Registration of Medicine, reports the written examination held at Portland, March 8-9, 1932. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Seven candidates were examined, all of whom passed. One physician was licensed by reciprocity. The following colleges were represented:

| College | PASSED | Year Grad | Per Cent |
|---|---|---|---|
| Yale University School of Medicine | | (1931) | 82.6 |
| Tufts College Medical School | | (1919) 77.6, (1930) | 85.9 |
| University of Michigan Medical School | | (1924) | 85.7 |
| Hahnemann Medical College and Hosp. of Phila | | (1931) | 85.6 |
| University of Toronto Faculty of Medicine | | (1930) | 86.3 |
| McGill University Faculty of Medicine | | (1924) | 85.7 |

| College | LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|---|
| Rush Medical College | | (1892) | N. Dakota |

## *Book Notices*

**Reports of the Committee Upon the Physiology of Vision. IX. Psychological Factors in Peripheral Vision.** By G. C. Grindley. Medical Research Council, Special Report Series, No. 163. Paper. Price, 1s. Pp. 49, with 8 illustrations. London: His Majesty's Stationery Office, 1931.

Factors accounting for the great difference between peripheral and central vision are of three kinds. They are physical, such as the distortion of images from oblique rays, retinal, due to the distribution of rods and cones, and central, due to the interpretation of the images in consciousness. The present report describes the author's experimental investigation of these central factors. An apparatus was arranged in which an observer fixed a light through an aperture while objects were exposed at angles of 20, 40, 60 and 80 degrees from the center of fixation by means of a projection apparatus. By means of a shutter, the time of exposure could be varied but was usually one-tenth second. Six psychologists were used as observers for about 800 readings, the images exposed being drawn as accurately as the visual impression would allow. The figures used were geometric figures consisting of combinations of circles and lines. As would be expected, the accuracy of observation decreased markedly with distance from the fixation point and with decrease in the size of the object. Objects of the same size appeared smaller in the periphery, possibly on account of the sparsity of receptors in this portion of the retina. Some observers drew figures quite unlike the one exposed, and here apparently a previously existing "perceptional pattern" was aroused by the figures shown. Sometimes only parts of the figure were observed, indicating that certain parts dominated others in the impression formed. The same effect was noted when several figures were exposed at once, some being observed while others were not. When an object had been previously observed a number of times, it was seen more easily or was wrongly seen in place of other objects not distinctly seen, indicating a "sensitization" to certain perceptional patterns. There was great variability in interpretation of the same figure seen on different occasions under identical conditions, especially in the part of the field where objects were just perceptible. The effect of time was tested by exposing the same object at 80 degrees for periods of from a hundredth to one second. Some correct observations were made in a hundredth of a second but the accuracy increased markedly up to one second. When other objects were exposed simultaneously nearer to the fixation point, a longer time was required to recognize the same peripheral figure correctly, evidently because the attention was diverted by the more central figures. If told in which part of the field the object was to be seen, most observers saw it with slightly greater accuracy, indicating the effect of a conscious effort of attention. In experiments to determine localization in the peripheral field, most observers showed a tendency to localize objects nearer to the fixation point than they actually are, the error being greater for objects placed farther in the periphery. Most of the central factors revealed by the experiments, such as those of attention, expectation and the tendency to interpret images in terms of known forms, apply to direct as well as to peripheral vision and the author concludes that no distinct differences can be claimed in the psychic processes involved in these two types of vision.

**Thomson and Miles' Manual of Surgery.** By Alexander Miles, M.D., LL.D., F.R.C.S., Consulting Surgeon, Royal Infirmary, Edinburgh, and D. P. D. Wilkie, M.D., F.R.C.S., Professor of Surgery, University of Edinburgh. Volume II: Extremities, Head, Neck; Volume III: Thorax, Abdomen Eighth edition. Cloth. Price, $3.80 each. Pp. 685, with 303 illustrations. Pp 578, with 177 illustrations. New York: Oxford University Press, 1931.

In volume II, the various fractures of the extremities, the head and the neck are considered in detail, with clear and illustrative roentgenographic and anatomic demonstrations. Injuries to the skull and the brain and disease processes are described rather briefly but to the point. Congenital malformations of the extremities and spinal column are considered with the accepted orthopedic measures indicated. The neck organs are described with the chief pathologic lesions found, their symptomatology, and a review of the accepted therapeutic measures. The general plan of considering the normal anatomic relations of the region under discussion is to be commended. In volume III the discussion of the thorax is rather hurried but probably is adequate for a manual. This volume covers the various intra-abdominal organs, pancreas, spleen and genito-urinary tract. Needless to say, only the high points can be even mentioned. Many surgeons probably would disagree with the authors in the included and the omitted material. The reaction to these two volumes is the same given for the first volume, in that a textbook of this character should be used mainly for review and not as an introduction to the field of surgery by the student.

**Über Klimatophysiologie.** Von Prof. Dr. A. Loewy, Schweizerisches Forschungsinstitut für Hochgebirgsklima und Tuberkulose in Davos. Paper. Price, 4.80 marks. Pp. 77, with 13 illustrations. Leipzig: Georg Thieme, 1931.

This is an abstract, for physicians and meteorologists, of lectures that appeared in the *Deutsche medizinische Wochenschrift* last year. According to Loewy, climate represents the sum of the atmospheric and terrestial conditions, typical of certain regions, which directly influence our well being. The effect of atmospheric conditions on metabolism and on bodily health is thoroughly studied; the effect of heat and cold on our moods is noted; the joys experienced by beautiful scenery are connected with benefits to health. While in general climates have been divided into warm and cold, Loewy especially takes up the study of the climates of high altitudes, the desert, the tropics, and that of the coast of the North Sea. The physiologic instruments employed in studying the skin and subcutaneous temperatures, in estimating the evaporation of moisture from the skin and the lungs, and for the measurement of the gaseous interchange in respiration are described and pictured. In the average climate, evaporation of moisture from the body in twenty-four hours is estimated at about 1,000 Gm. Of this moisture, 75 per cent comes from the skin and 25 per cent from the breath. In desert climates the daily total amounts to nearly 3 liters and the skin-breath proportion is as 85 to 15. In high altitude climates the ratio is 60 to 40. The coast climate of the North Sea is recommended for anemia and for poorly developed children. The stimulating effect on the skin of the cool temperature, of the air movement and of radiation are considered responsible for the beneficial effects.

The sun's rays and their effects are analyzed. Sunshine has a direct influence in stimulating the growth of children; hence height is increased in summer, whereas gain in weight is more noticeable in the winter months. A review is given of the literature on the effects of ultraviolet radiation on the blood and its power to lower the blood pressure. The ultraviolet irradiation of food is discussed. It is noted that the hay grown at high altitudes has a greater vitamin content, when fed in winter, than the fresh pasturelands of lower altitudes have in summer. The shorter ultraviolet rays can inhibit the development of goiter, and therefore residence in high altitudes must be considered in the prevention of goiter.

Reference is made to the easy acclimatization to altitude of the recent explorers of Everest. It is of interest that Noel in his "Story of Everest" noted, at extreme altitudes, mental depression, irritability, inertia, the dislike of meat by the climbers, and other symptoms, which led Gale of Glasgow to compare their condition to that of hyperthyroidism. Gale suggested that the best air pilots and future members of Everest expeditions should be men of "slow pulse, solid countenance and quiet speech"; in other words, those with slight hypothyroidism. Loewy calls attention to the purity of the atmosphere of high altitudes as a factor in the lessening of allergic conditions such as asthma, but he points out that a similar situation exists in sea climates. The well known increase of red blood corpuscles and of hemoglobin is described, but the lymphocyte increase of altitude is not mentioned. At even moderate altitudes the cholesterol content of the blood is found to be increased, and in different organs the calcium content was found increased at the expense of the potassium. Anesthetics, such as ether, appear to work more quickly at altitudes, and alcohol is less intoxicating and disappears more quickly from the blood. Desert climates, such as the climate of Egypt, have not been fully studied, but they induce an increase in red corpuscles without a corresponding proportionate increase of hemoglobin as in high altitudes. The systolic blood pressure is also lowered in the normal as well as in arteriosclerotic and nephritic patients. With moderate exercise, however, the blood pressure rises rapidly. A chart is given showing how Europeans adapt themselves to tropical heat. The chemical changes in the blood in the tropics are the opposite to those of elevated climates, the cholesterol and calcium being markedly decreased.

The little book is of unusual interest, containing a greater mass of information than the size would promise. Books on climate are rare, so one welcomes a work in which the physiology of climate can be found so well related and reviewed. The maxim of Montesquieu is still true: "The empire of climate is the most powerful of all empires."

**Psychology at Work.** By Lois Hayden Meek, Floyd H. Allport, and Others. Edited by Paul S. Achilles. Cloth. Price, $2.50. Pp. 260, with illustrations. New York: Whittlesey House, McGraw-Hill Book Company, Inc., 1932.

This is a symposium planned to present the participation of psychology in daily life. All the authors are teachers who are known for their contributions to this field. Each of the chapters is of importance to the medical profession, but especial interest attaches to the chapter by Dr. Walter R. Miles on "Psychology and the Professions." He encourages particularly the development of clinics in which medicine and psychology cooperate for the handling of disease that comes so definitely in both fields. There are many practical suggestions in this book of importance to workers charged with the selection of personnel and with obtaining maximum outputs consistent with good health in industry.

**Klinische Mikroskopie: Atlas und Leitfaden.** Von Dr. A. Kowarski. Paper. Price, 42 marks. Pp. 172, with 323 illustrations. Berlin: Urban & Schwarzenberg, 1932.

During the past year, many books on laboratory diagnosis have been offered to the medical profession. In each case the author has sought to justify his effort by some new departure in presenting the subject. The present work deals exclusively with microscopic investigations of blood, puncture fluids, secretions, excretions and products of diseased organs. The text differs in no way from the material found in any of the recent comprehensive works on laboratory diagnosis except that continuity is preserved by omitting everything but clinical microscopy. The book is concise and contains the essential information which the physician should know of the clinical material usually submitted for laboratory examination. It would seem that in a textbook of this nature a chapter on microscopy in general could have been added profitably. The author devotes quite a large chapter to the examination of feces, but it is doubtful whether the information presented justifies this detailed treatment. The discussion on the examination of the blood is good, although many of the instruments are not generally available to the physician in America. The organization of the book is excellent. On the margins are numbers, which refer the reader to colored illustrations in the back of the book. About half of the book is an atlas of illustrations in from one to four natural colors. The author has chosen this because he feels that photography does not lend itself to adequate illustration of such specimens. If this work was intended for the physician, the author must presume that he has other books on clinical pathology, for the text covers only the microscopic phase of laboratory investigation. The chief value of the work is the atlas, as there does not appear to be any feature of the text that is not contained in the latest books on laboratory diagnosis in this country.

**The Work, Wealth and Happiness of Mankind.** By H. G. Wells. In two volumes. Cloth. Price, $7.50 per set. Pp. 1-454 and 455-924, with illustrations. Garden City: Doubleday, Doran & Company, Inc., 1931.

This constitutes the third contribution of the great H. G. Wells to his account of modern knowledge. His previous works on the history of our civilization and on the science of life represent special studies from the point of view of history and of science of what man has learned. His present book deals primarily with economics. It is written with the literary technic for which the author is so well known. It shows a tremendous grasp of the available information. The book reveals, moreover, an analysis of trends of our civilization including our economic waste that is highly instructive when such a study is so much needed. The books are beautifully printed and handsomely illustrated and enlightening.

**Grundriss der Entwicklung des Menschen.** Von Dr. Alfred Fischel, o. Professor der Embryologie und Vorstand des Embryologischen Institutes der Wiener Universität. Paper. Price, 11 marks. Pp. 141, with 117 illustrations. Berlin: Julius Springer, 1931.

Fischel's Lehrbuch der Entwicklung des Menschen was published by Springer in 1929. In the review in The Journal it was characterized as one of the best works on the subject available. But for medical students it was rather long (822 pages). This smaller book is a condensation of the work: it attempts to put into clear and available form those fundamental facts and principles which every medical student and every physician must know. The author has succeeded admirably. The book can be highly recommended to students and perhaps will suggest to teachers of medical students in embryology and other subjects that we might have better students and physicians if courses were less encyclopedic in content and thorough training in essentials more simply insured.

**Communicable Diseases for Nurses.** By Albert G. Bower, M.D., Head of Department of Communicable Diseases and Associate Professor of Medicine, University of Southern California, and Edith B. Pilant, R.N., Superintendent of Nurses, Communicable Disease Section, Los Angeles General Hospital. With a foreword by Elizabeth F. Miller, R.N. Second edition. Cloth. Price, $3. Pp. 358, with 35 illustrations. Philadelphia: W. B. Saunders Company, 1932.

The first edition of this volume appeared in 1929. Since that time enough new material has been developed to warrant a complete rewriting of the text; moreover, on the request of several nurses, the authors have added a chapter on impetigo. Some attempt has been made to refrain from the use of technical terms, although the very nature of the subject makes this difficult. However, each time a technical term is used a definition is provided. The volume is exceedingly practical, giving complete information as to aseptic technic and the avoidance of contamination. The chapter on the care of communicable diseases in the home is followed by a discussion of various infectious diseases in systematic order, beginning with definition and following with etiology, symptoms, diagnosis, treatment and nursing care. A good glossary and index complete the volume.

**Das Chlorophyll als Pharmakon.** Von Professor Dr. Emil Bürgi. Paper. Price, 6.40 marks. Pp. 84, with 28 illustrations. Leipzig: Georg Thieme, 1932.

At least seventy workers have studied the pharmacology of chlorophyll since 1913, when Willstätter established definitely its close chemical relationship to hemoglobin. Various physical and chemical changes have been described, especial attention having been devoted to the circulation, blood picture, metabolism and growth. This review of results is illustrated by a variety of protocols and figures, especially from the works of the author, the pioneer in the field. He is intrigued by the conception of "leaf-green" as a "tonic" and growth stimulating vitamin. Strengthening of the heart (not decompensated) is also claimed. Increasing importance is thus ascribed to the green vegetables in both dietetics and therapeutics.

# Medicolegal

## Fracture of Coccyx; Refusal to Submit to Operation

*(Indian Territory Illuminating Oil Co. v. Bates (Okla.), 1 P. (2d) 750)*

As the result of an accident occurring in the course of his employment, Bates fractured his coccyx. His employer offered to pay for an operation to repair the fracture. Bates refused, claiming that he had been advised by physicians not to be operated on. Notwithstanding the employer's tender of an operation, however, the Industrial Commission of Oklahoma awarded compensation. The employer thereupon appealed to the Supreme Court of Oklahoma, contending that the claimant's disability was the direct result of his failure to submit to medical and surgical treatment which the employer had tendered to him; that the claimant had no right to refuse to submit to an operation "that all the medical testimony recommended should be performed"; that the operation was not dangerous and would restore in a short time the claimant's ability to perform manual labor; and that claimant's employer could not be required to continue indefinitely the payment of compensation.

A medical witness for the claimant testified that the removal of the coccyx entailed the danger of a permanent fistula and that it would leave a certain amount of disability. On behalf of the employer a physician testified that by far the greater number of patients who complain of injury to the coccyx and of pain in it are of highly neurotic, nervous types, with whose coccyges there is absolutely nothing wrong as far as can be determined by physical examination or by use of the roentgen ray. Patients of this class should never be operated on, since they never get well. In other patients, the pain complained of is due to some definite pathologic condition, which, because of the proximity of a sensitive plexus of nerve groups, which becomes irritated by the trauma, causes the patient to become nervous and irritable. Patients of this class should be operated on, because they always get well. The claimant, in the opinion of the witness, belonged to this latter class. The roentgen ray showed a very short angularity of the distal half of his coccyx, an angle of about 90 degrees to the sacrum. An operation in his case would enable him to go back to work in three or four weeks.

The rule previously stated by the Supreme Court of Oklahoma is: "If the operation is not attended with danger to life and health, or extraordinary suffering, and if, according to the best medical or surgical opinion, the operation offers a reasonable prospect of restoration or relief from the incapacity from which the workman is suffering, then he must either submit to the operation or release his employers from the obligation to maintain him." *Henly v. Oklahoma Railway Co.*, 81 Okla. 224, 197 P. 488. The real question in this case, said the Supreme Court, is whether the refusal of the claimant to submit to the surgical operation which was tendered is reasonable. It is a pure question of fact, determinable under the workmen's compensation act of Oklahoma by the Industrial Commission. It is for the commission to determine it from all the evidence, facts and circumstances appearing at the trial, including the testimony of the claimant as well as that of medical experts. The finding of the Industrial Commission with respect to this matter, like its determination of any other fact, if there is any competent evidence reasonably tending to support it, is binding on the court. Inasmuch as the commission found that the claimant was not unreasonable in his refusal to be operated on, and since there was competent evidence reasonably tending to support that finding, the determination of the commission was upheld. The question of the unreasonableness of a claimant's refusal to submit to a surgical operation, however, said the court, should not necessarily be confined to its unreasonableness on the date when the operation was tendered by the employer and refused by the employee. The question should be open for further investigation at any time, by the employer, or by the commission on its own motion, dependent on a change in the claimant's condition and his progress toward restoration to health, and the reasonableness of his attitude at the time toward submitting himself to a further tender of a surgical operation.

The award of the commission in favor of the claimant was affirmed.

**Expert Testimony: Opinion Evidence.**—The chief value of expert evidence, in the judgment of the Supreme Court of Missouri, Division No. 1, lies in the fact that the witness possesses superior knowledge of the subject under consideration and by reason of his study, training and experience is able to discern and trace the causal connection, if any, between successive events. The expert witness can aid the jury in determining whether an alleged injury was the result of the cause to which it is attributed or of a different cause. The witness should be left free in the exercise of all his faculties in so doing. He should not be told to exclude matters which may be important. It is proper for a medical expert to testify and give his opinion either from facts within his own knowledge and observation or from hypothetical facts, or from the two combined. Where the witness has personal knowledge of the subject matter, a hypothetical presentation is unnecessary; an opinion based on and supported by the personal observation and knowledge of the witness is more likely to be correct than an opinion based on facts which are only hypothetical. A hypothetical question should include all the facts essential to the theory of the party propounding it. Undisputed facts, when material to the issue, must always be included in it. When, in submitting to witnesses a hypothetical question designed to elicit their opinions concerning the cause of an abortion, the witnesses were instructed to assume all of the facts stated in the hypothetical question and to eliminate any other cause, the court erred in not sustaining a timely objection by the defendant to the inclusion of the instruction to eliminate every cause except those embodied in the question.—*De Donato v. Wells (Mo.), 41 S. W. (2d) 184.*

## COMING MEETINGS

American Association for the Study of Goiter, Hamilton, Ontario, June 14-16. Dr. J. R. Yung, 670 Cherry St., Terre Haute, Ind., Secretary.

American Neurological Association, Atlantic City, June 6-8. Dr. Henry Alsop Riley, 117 East 72d Street, New York, Secretary.

American Ophthalmological Society, New London, Conn., June 27-29. Dr. Emory Hill, 501 East Franklin Street, Richmond, Va., Secretary.

American Orthopedic Association, Toronto, Canada, June 15-18. Dr. DeForest P. Willard, 1916 Spruce Street, Philadelphia, Secretary.

Conference of State and Provincial Health Authorities of North America, Washington, D. C., June 2-6. Dr. A. J. Chesley, State Board of Health, St. Paul, Minnesota, Secretary.

Maine Medical Association, Rangeley, June 16-18. Dr. Philip W. Davis, 22 Arsenal Street, Portland, Secretary.

Massachusetts Medical Society, Boston, June 8-10. Dr. Walter L. Burrage, 182 Walnut Street, Brookline, Secretary.

Medical Library Association, San Francisco, June 20-22. Miss Marjorie J. Darrach, 645 Mullett Street, Detroit, Secretary.

Montana, Medical Association of, Miles City, July 13-14. Dr. E. G. Balsam, 208 North Broadway, Billings, Secretary.

National Tuberculosis Association, Colorado Springs, June 6-9. Dr. Charles J. Hatfield, 7th and Lombard Streets, Philadelphia, Secretary.

New Jersey, Medical Society of, Atlantic City, June 15-17. Dr. J. B. Morrison, 66 Milford Avenue, Newark, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 27-29. Dr. Frederick Epplen, 1215 Fourth Avenue, Seattle, Secretary.

South Dakota State Medical Association, Watertown, June 20-22. Dr. John F. D. Cook, Langford, Secretary.

Western Branch of the American Urological Association, Portland, Ore., July 1-2. Dr. F. S. Dillingham, 548 S. Spring Street, Los Angeles, Secretary.

West Virginia State Medical Association, Parkersburg, June 21-23. Mr. J. W. Savage, Professional Building, Charleston, Executive Secretary.

# *Current Medical Literature*

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

**16:** 227-438 (March) 1932

*Cancer and Tuberculosis with Some Comments on Cancer and Other Diseases. E. B. Wilson and Helen C. Maher, Boston.—p. 227.

*Carcinoma of Penis, with Report of Sixty-Seven Cases. W. E. Leighton, St. Louis.—p. 251.

*Lymphatic Leukemia with Thymic Enlargement: Brief Review of Literature with Case Reports. L. F. Craver and W. S. MacComb, New York.—p. 277.

Distribution of Blood Cholesterol in Cancer. Helen R. Downes and G. T. Pack, New York.—p. 290.

*Blood Changes in Malignant Diseases. C. N. Myers and B. Throne, New York.—p. 297.

Transplantation of Rous Fowl Sarcoma Number I into Guinea-Fowls and Turkeys. M. J. A. des Ligneris, Johannesburg, Transvaal, South Africa.—p. 307.

Genetic Studies on Transplantation of Tumors. J. J. Bittner, Bar Harbor, Maine.—p. 322.

Further Studies on Inactivation of Tumor-Producing Viruses by Means of Dyes. Margaret Reed Lewis and W. R. Lewis, Baltimore.—p. 333.

*Recovery of Active Agent of Rous Chicken Sarcoma After Its Intravenous Injection into Fowls. M. J. Sittenfield, Balbina Johnson and J. W. Jobling, New York.—p. 345.

*Relation of Hypophysis to Growth of Malignant Tumors: I. Effect of Hypophysectomy on Transplanted Mammary Carcinoma in White Rat. H. A. Ball and L. T. Samuels, Los Angeles, with assistance of Winea Simpson.—p. 351.

*Metabolism of Sulphydril Compounds in Tumor Tissue. A. Goerner and M. Margaret Goerner, Brooklyn.—p. 360.

Influence of Various Preparations of Lactic Acid on Transplanted Tumors: I. Action on Sarcoma Thirty-Nine. I. A. Parfentjev, W. Devrient, V. D. Suntzeff and B. Sokoloff, St. Louis.—p. 366.

Osteogenic Sarcoma of Dog: Pathologic and Roentgenologic Observations. W. H. Feldman and Frances A. Ford, Rochester, Minn.—p. 377.

*Undifferentiated Round-Cell Sarcoma of Ilium (Ewing Tumor) Containing Hemopoietic Elements. N. W. Roome and P. A. Delaney, Chicago.—p. 386.

*Papillary Mixed Tumor of Body of Uterus. G. H. Kistler, Chicago.—p. 399.

Diffuse Hemangioma of Spleen. E. Kellert, Schenectady, N. Y.—p. 412.

Spindle-Cell Sarcoma of Thigh: Case Report. S. W. Vernick and J. R. Lisa, New York.—p. 419.

Method for Measuring Radon Seeds. A. J. Allen.—p. 423.

**Cancer and Tuberculosis.**—According to Wilson and Maher, there seems to be little or no evidence in favor of an antagonism or dissociation between cancer and tuberculosis and a considerable variety of evidence in favor of a slight degree of positive association between the two, but until better estimates of morbidity rates are available one may not be dogmatic over the matter and may well admit that for practical purposes cancer and tuberculosis may be regarded as independent. There does seem to be considerable evidence that cancer of the esophagus is associated with pulmonary tuberculosis, as might perhaps be natural if the condition resulted in long-continued malnutrition. At present there seems to be no material on which to make a clear-cut discrimination between the association of the lesions which should lead to the judgment that they tend to originate in the same persons because of constitutional diathesis and that association which might result merely from an invasion of one of the processes by the other or a lowered resistance to the progress of one of the diseases owing to debilitation by the other.

**Carcinoma of Penis.**—A summary of the sixty-seven cases of carcinoma of the penis reported by Leighton reveals that twenty-four patients refused operation or for some other reason were not treated, while forty-three received treatment. Of the patients refusing treatment, three are known to have died of cancer and one of an unknown cause; nineteen have not been heard from, and one was operated on elsewhere. Ten patients had had a partial amputation before coming to the clinic, and in all of these recurrence of the cancer had taken place. Of the forty-three patients receiving treatment, four received roentgen rays or radium. Of these, three died and one is untraced. Five biopsies showed carcinoma. In one of these cases, amputation was performed elsewhere and the patient was reported well a year later. The condition of the other four is unknown. Thirty-four patients were operated on. Of these, five have not been heard from. Fourteen died, two postoperatively and three of recurrence; nine lived from one month to eighteen years, dying of other causes than cancer. Nineteen are living from six months to twenty-five years. A study of the pathologic specimens with respect to the malignancy of the cancer according to Broders' classification revealed that five were in group I, nineteen were in group II, six were in group III, and one was in group IV. There were only three deaths from recurrence in the series. In each of these there was a metastasis in the inguinal lymph nodes at the time of operation. In one there was a group II tumor and in one a group III tumor. On the other hand, five patients with group II tumors with inguinal metastases at the time of operation are still alive and free from recurrence.

**Lymphatic Leukemia with Thymic Enlargement.**—Craver and MacComb state that tumefaction of the thymus in association with lymphatic leukemia, while rare, is a definitely recognized variant of that disease and is probably the result of leukemic infiltration of the organ. In cases of thymic tumor, the blood and lymph node system should be carefully observed for evidence of leukemia. The thymic tumors associated with lymphatic leukemia are radiosensitive. In younger individuals the leukemic process is likely to be of a more acute type. Therefore, while the disease is responsive in some measure to irradiation, great caution in selection of dosage is needed to avoid precipitating such exacerbations as an increase of a hemorrhagic tendency or an acute leukopenia. When a hemorrhagic tendency or a leukopenia is already established, it would seem best to withhold treatment until one can judge the gravity and acuteness of the disease.

**Blood Changes in Malignant Diseases.**—Myers and Throne report studies which indicate that in cancer during the earlier decades of life the index for plasma/whole blood and serum/whole blood is slightly higher than in the later decades of life. It furthermore appears that the indexes are slightly lower for females in the early decades of life, with a gradual increase at the fifth decade. There is some difference in the averages for the males and females. For epithelioma of the skin, the averages are almost identical with those found for cancer situated elsewhere. Psoriasis was one of the diseases selected for control experiments because in certain instances an association has been suggested between psoriasis and abnormal fat metabolism. A comparison of the results obtained for cancer with those obtained for psoriasis indicates that the index is slightly higher for psoriasis. The cholesterol indexes for eczema, dermatitis and a group of miscellaneous diseases, with the exception of xanthoma, were similar to those obtained for cancer. It would appear, therefore, that cholesterol indexes offer nothing of value for the detection of neoplastic conditions. Certain other abnormal conditions found in the blood have offered evidence that there is a disturbance in the biochemical and the biophysical metabolism involving fats, carbohydrates and nitrogen.

**Recovery of Active Agent of Rous Chicken Sarcoma.**—Sittenfield and his associates describe experiments in which they demonstrated that the untreated blood of chickens injected intravenously with from ten to twenty tumor-producing doses of the Rous chicken sarcoma is infective for forty-eight hours but noninfective thereafter until the terminal stages of the disease. Extracts of the blood of chickens inoculated intravenously with similar doses of the active filtrate remain infective for eight days and then become noninfective until late in the disease. The inhibiting substances present in the blood are not sufficient to protect the chicken against more than one tumor-producing dose when it is given intravenously.

**Relation of Hypophysis to Growth of Malignant Tumors.**—Ball and Samuels noted that in a group of hypophysectomized albino rats largely composed of males, the growth rate of a transplantable mammary carcinoma was greatly reduced. If hypophysectomy was performed after development of the tumor, there was an immediate retardation of the rate of neoplastic growth. In the series, hypophysectomy did not cause complete cessation of tumor growth.

**Metabolism of Sulphydril Compounds in Tumor Tissue.**—*White rats with Flexner-Jobling rat carcinoma transplants* showed a decrease in glutathione content of liver and tumor when placed on a low cystine diet by the Goerners. This decrease was more marked in the liver tissue than in the tumor. Liver tissue seemed to lose glutathione more readily than tumor tissue. On a normal diet, tumor tissue varied more widely as to glutathione content than liver. Animals placed on a low cystine diet showed a larger number of unsuccessful transplants than those on a normal diet.

**Undifferentiated Round-Cell Sarcoma of Ilium.**—Roome and Delaney report a case of round-cell sarcoma of the ilium, with extensive skeletal and few visceral metastases. It is classified as an atypical Ewing sarcoma. Special stains show the presence of hematopoietic elements in the tumor. The possibility that the tumor is a borderline Ewing sarcoma, merging into a myeloid stem-cell tumor (hemocytoblastoma), is discussed.

**Papillary Mixed Tumor of Body of Uterus.**—Kistler describes a mixed tumor of the body of the uterus and adnexa, *unusual in that it contained both epithelial and mesothelial* derivatives. Narrow branched papillae with slender fibrous connective tissue stalks covered by columnar cells constituted most of the tumor. In the fibrous stalks were bundles of smooth muscle and masses of hyaline cartilage. Edematous or *embryonal myxomatous tissue was not a constituent of this* mixed tumor of the uterus. The cartilage tissues were distributed in multiple small focal masses, which differed markedly in size and in degree of differentiation. Such variations in structure suggest the origin of cartilage islets from the connective tissue stroma of the tumor.

Syphilis and Gonorrhea in Upstate New York. A. Pfeiffer and H. W. Cummings, Albany, N. Y.—p. 459.
*Precipitin Experiments with Yellow Fever Virus. M. Frobisher, Jr., Bahia, Brazil, South America.—p. 485
Presence of Thermophils in Raw and Pasteurized Milk in Baltimore with Record of New Species. V. Zavagli, Baltimore.—p. 498.
Formalin Treatment of Transplantable Rat Carcinoma. R. E. Gardner and R. R. Hyde, Baltimore.—p. 509.
An Evaluation of Egg-Count Data in Hookworm Infestation. W. C. Earle and C. R. Doering, Boston.—p. 513.
Dried Infectious Monkey Serum as Antigen in Yellow Fever Complement Fixation. N. P. Hudson, Chicago—p. 557.
Some Observations on Nyssorhynchus Group of Anopheles (Culicidae) of Panama. D. P. Curry, Panama, R. P.—p. 566.
Climate as Factor in Health of Man. C. A. Mills, Cincinnati.—p. 573.
Geographic Variations in Female Sexual Functions. C. A. Mills, Cincinnati.—p. 593.

**Serologic Reactions of Meningococcus Strains.**—Kirkbride and Cohen record the serologic reactions of 451 strains of the meningococcus. As a result of long continued artificial cultivation, the state standard groups I and III strains have become very similar in agglutination and agglutinogenic reactions. It is considered important, however, for purposes of therapeutic serum production, to continue to recognize both groups. A strain recently isolated in this country is allied with both the federal and the English strains and may represent a broad group which includes all three. Wide variation was obtained in the agglutination titers of serums from rabbits immunized with carefully selected strains from recent cases of meningitis. None of these strains were apparently markedly superior antigenically to the state strains used for more than thirteen years in serum production. The state standard strains compared favorably in the valence of their serologic reactions and, in general, in antigenic activity with the federal strains. The groups I and III strains of the two standards were not closely related. The authors believe that further laboratory study and clinical data are required before replacement of present state strains by recently isolated strains is made in the routine production of the therapeutic serum.

**Precipitin Experiments with Yellow Fever Virus.**—Using a technic which he describes, Frobisher found that the virus of yellow fever in mosquitoes engendered in rabbits neither precipitins nor protective bodies against the same virus contained in monkey blood. Large amounts of the virus from the blood of infected monkeys failed to engender in rabbits demonstrable precipitins against the virus in mosquitoes, but in relatively tiny amounts engendered protective bodies against monkey blood virus. Using an antimonkey precipitating serum capable of detecting one part of monkey serum in 20,000 parts of physiologic solution of sodium chloride, the author was unable to demonstrate the presence of monkey protein in Aedes aegypti later than the fourth day after their blood meal.

Primary Choriocarcinoma of Fallopian Tube: *Report of Case.* H. E. Stein, New York.—p. 416.
Comparative Study of Mercurochrome and Hexylresorcinol as Antiseptics During Labor. H. B. Henderson, Denver.—p. 430.
Chinese Customs and Traditions of Childbirth with Birth Statistics for San Francisco. J. Shiang-Min Lee, San Francisco.—p. 434.

**Endometrial Hyperplasia and Carcinoma of Body of Uterus.**—Taylor believes that whether from a practical standpoint endometrial hyperplasia of the body of the uterus is to be regarded as precancerous and treated as such must remain an open question. The relative frequency of hyperplasia undoubtedly indicates that the individual patient with the disease is reasonably safe. Nevertheless it appears that when the hyperplasia is at all marked, the possibility of a predisposition to the development of cancer should be considered and the case regarded with the same degree of suspicion now bestowed on the diffuse forms of hyperplasia of the breast epithelium. In patients of the menopause age and older, an adequate dose of radium is particularly indicated, certainly as the most efficient method of controlling bleeding, possibly as a prophylactic measure against the development of cancer.

**Treatment of Carcinoma of Cervix.**—Adler reports the results he has obtained in the treatment of carcinoma of the cervix by vaginal hysterectomy and radium, which is his routine method. However, he emphasizes the fact that in the treatment of cancer one must not be dogmatic but eclectic and he does not adhere by any means to the vaginal laparotomy. But in these cases he likewise inserts radium into the parametrial wound cavity immediately after the operation as after the vaginal operation. He believes that one must not adhere to a *single method but choose for each case the adequate procedure.* Gynecologists should break off with the old method of gathering statistics. Every gynecologist should take up in his statistics all cases which he sees and all cases in which the patients are living free of recurrence after five years; no matter *whether they were operated on by the vaginal or the abdominal* method or treated with radiation only, all these must be considered as permanent cures. In this way one will get a correct picture of the value of the treatment used in different places by different men. If one examines in this sense the author's material from 1920 to 1926, a proportion of 36 per cent of absolute cures (five years) is obtained. This encourages him to adhere to the path he has taken and to request an examination and trial of the method of treatment which he has developed.

**Pregnancy and Labor Complicated by Fibroid Tumors.**—Watson states that while fibroid tumors may constitute a major complication of pregnancy, labor and the puerperium, the smaller tumors usually permit the patient to proceed to term and deliver normally or with ordinary obstetric assistance. Every patient with fibroids of significant size requires careful watching and guiding during her pregnancy. The most frequent complication during pregnancy is red degeneration. While in some instances symptoms of this may be so acute as to necessitate surgical intervention in the course of the pregnancy, in the majority of cases the patient can be carried to term and delivered by cesarean section followed by myomectomy or hysterectomy. Or she may be delivered by the vagina and a subsequent myomectomy or hysterectomy be done. The size of the tumor may necessitate removal before term, but in the absence of acute symptoms time should be given to see whether the abdomen will not accommodate it.

**Treatment of Occipitoposterior Positions.**—In the treatment of occipitoposterior position, Danforth prefers the method of manual rotation and forceps to forceps rotation for the following reasons: 1. By using the hand, the operator is able at all times to know whether the head is responding to manipulation or not. 2. Should the first grip of the head be imperfect and should the operator feel the skull giving or bending under his fingers, the grip can be altered or shifted a little to prevent this. 3. If rotation is not easily accomplished at the level at which the head is found, the head may easily be shifted upward or disengaged if necessary. If disengagement is found necessary, prolapse of the cord must be watched for. 4. There is a notable freedom from deep upper vaginal tears, which are rather likely to occur in forceps rotation. 5. By the method described, only the right hand is used, regardless of the side on which the occiput lies. This permits the introduction of the left blade of the forceps first in all cases and obviates the awkward readjustment of the handles of the instrument when the right blade is introduced first. It reduces intravaginal manipulation to a minimum. The use of tenacula or other instruments to hold the occiput in the anterior position is unnecessary. The assistance of the external hand is of great value. The author emphasizes the fact that the following conditions, in addition to those usually given in standard textbooks for forceps, should obtain before one proceeds to manual rotation and forceps: 1. The head must be engaged. If molding is necessary, this must already have occurred. 2. The second stage should not have been allowed to proceed so long that a contraction ring has formed. 3. Ether anesthesia is requisite for the production of relaxation of the uterine musculature. With the lesser degree of relaxation accompanying gas anesthesia, success is much more difficult of attainment. The administration of ether may be preceded and followed by ethylene or nitrous oxide, so that the duration of ether anesthesia may be only a matter of a few minutes. After rotation is accomplished, one returns to ethylene.

**Modification of Aschheim-Zondek "Pregnancy Test."**—In Brown's modification of the Aschheim-Zondek test, from 2 to 5 cc. of serum is injected intravenously into the ear vein of a virgin female rabbit. Approximately 10 cc. of whole blood is obtained from the patient, and the serum is removed. The serum is allowed to stand for at least four hours or overnight before injection, as very fresh serum was found to be toxic and might cause death shortly after injection. The average effective amount of serum was found to be 1 cc. per 600 to 700 Gm. of body weight. Rabbits weighing from 600 to 2,150 Gm. are used. Animals weighing between 1,500 and 2,000 Gm. give the most constant results. The rabbits are operated on or examined post mortem from twenty-four to thirty-six hours after injection and the reaction can usually be determined by gross examination. Microscopic examination is used to check the gross observations. The rabbit can be used again at the end of three weeks. The earliest grossly positive reaction is observed at thirteen hours. Several of the animals of the author's preliminary series died before thirteen hours had elapsed. The period of gestation varied from three weeks to seven months. Serums from five patients not pregnant were used and gave negative results. In a doubtful case of pregnancy, three tests were performed and were all negative. A case of hydatidiform mole gave a strongly positive reaction and was found to be negative three weeks later. The reactions of the twenty-five positive specimens examined in the preliminary series were as follows: Eighteen were grossly positive; five were doubtful grossly but positive microscopically (rabbits died in less than thirteen hours); one examined post mortem at twenty-five hours was doubtful grossly but positive microscopically; one died thirty minutes after injection and showed no reaction. The reaction to the use of serum intravenously is found to be definitely more marked and to appear in a shorter time than when urine is used intravenously.

**Erosion, the Colposcope and Carcinoma of the Cervix.**—Ries calls attention to the fact that, in order to lessen the deplorable carcinoma mortality, various propositions have been made in the direction of preventive surgery, such as suture of all lacerations of the cervix, amputation of the cervix, or even vaginal hysterectomy on every woman of carcinoma age. All of these so-called protective methods fail to reach the bulk of carcinoma candidates, because they involve an operation. They furthermore appear largely unnecessary, because they would remove many organs which never would have developed carcinoma. But it would be entirely rational to invite all women to regular colposcopic examinations. As these are simple and painless and require little time, they ought to be consented to readily and repeatedly. The colposcope would then lead to the discovery of carcinomas at such early stages that extensive operations would not be needed. The fight against uterine cancer, of which carcinoma of the portio represents a large proportion, could thus be waged with increased chances of success. The fundamental difficulty to be overcome has always been the indifference of the patients. It is necessary to acquaint them again and again with the risks of tumor development, but it is also necessary to inform them of simple improvements in the means of diagnosis in order to break down their fears of painful procedures and interest them in ways and means of protecting themselves. The author believes that a colposcopic examination must come to be part of every periodic health examination and of every examination for life insurance, and should be as familiar and routine as a urinalysis and a blood examination.

**Spinal Anesthesia in Abdominal Obstetric Operations.**—According to Eades, spinal anesthesia has a definite place in abdominal obstetric surgery when the use of general inhalation anesthesia is contraindicated. The method is safe only with judicious selection of risks, a careful technic of induction, close observation of the patient during anesthesia, and preparedness for any unfavorable reaction. Spinal anesthesia is contraindicated in desperate risks or in conditions in which either shock or hemorrhage is present.

Practical Device for Radiographic Examination of Optic Foramen. R. Argañaraz, Buenos Aires, Argentina, South America.—p. 230.

**Operations for Glaucoma.**—Friedenwald calls attention to the fact that sudden reduction of intra-ocular tension, as in operations that empty the anterior chamber, results in congestion of the ciliary body. The state thus produced resembles that which is found in acute glaucoma. To combat this effect, the use of retrobulbar injections of solution of epinephrine is advocated.

**Tribrom-Ethanol ("Avertin") as an Anesthetic in Eye Surgery.**—Davis presents the advantages of "avertin" anesthesia in eye operations. The eye is quiet, the conjunctiva is pale and bleeding is reduced. The extra-ocular muscles are relaxed. Intra-ocular tension is reduced, often very materially. The induction of anesthesia is considered ideal, requiring usually from fifteen to twenty minutes after administration by rectum of 0.1 mg. per kilogram of body weight. The postanesthetic period is usually quiet and free from nausea. No deaths have occurred in the author's series of 135 cases. Overdosage, overheating of the drug, and improper postoperative care are given as the causes of danger in use of the drug.

**Fate of Foreign Bodies That Remain Inside Eye.**—Fejer reports three cases in which metallic foreign bodies were retained in the eyeball from five to eighteen years. In two eyes the vision remained useful. In the third case a shrunken globe was removed because of inflammatory symptoms, and histologic examination showed a recent suppurative process due to the presence of the foreign body.

**Influence of Insulin on Motility of Urinary Bladder.**—Lindquist reports that subcutaneous injection of insulin causes an increase in motility and tone of the unanesthetized female dog's urinary bladder. Micturition with or without convulsions may occur at the height of the hyperactivity following insulin. The recorded increases in bladder activity were not due to changes in intra-abdominal pressure. The effect of dextrose administered intravenously on insulin hyperactivity is not constant, but inhibition is frequently noted. In the author's series of dogs the majority showed a considerable degree of urinary bladder motility, prior to injection of insulin.

**Relation of Hypophysis and Ovaries to Experimental Uterine Bleeding.**—Saiki caused menstruation-like bleeding from the uterus by the injection into immature monkeys of an extract of hypophysis (eleven positive cases in twelve). Intervals between the last injection and the external bleeding were from four to nine days, and the duration of the external bleeding was from five to seven days. This menstruation-like bleeding was produced two or three times at short intervals. Castrated monkeys did not bleed microscopically or macroscopically during or after the injection of the anterior lobe extract. The ovaries of the monkeys in which bleeding was produced by the treatment showed no ripe follicles or corpora lutea but there was some difference in the ovaries, as shown by experiments in which the follicles were larger in the ovaries removed after the injections than in the control ovaries. This experimental menstruation-like bleeding was similar to that found in normal monkeys, in which regular menstruation may occur without rupture of a follicle or presence of a corpus luteum. The uteri from the positive cases showed bleeding from an interval stage of the endometrium. A castrated immature monkey, which did not bleed following injections of hypophysis extract, showed menstruation-like bleeding subsequently after a course of injections with follicular hormone. An immature monkey treated with a subeffective dose of hypophysis extract, and then spayed, showed bleeding after removal of the ovaries. Bleeding which normally follows treatment with hypophysis extract was postponed by injections of follicular hormone. It is assumed from these experiments that the experimental menstruation-like bleeding results from an alteration of the endometrium, which occurs when the effect of follicular hormone is removed.

**Quantitative Study of Placental Transmission.**—In a study of placental transmission in a series of rabbits observed during the last third of gestation, Lell and his associates found that following the injection of fetuses in utero with 3 mg. of phenolsulphonphthalein per fetus there is an output during a six-hour period of more than 30 per cent of the dye from the fetus at the twenty-second day of pregnancy, while less than 15 per cent of the dye is excreted from the fetus at the twenty-ninth day. If allowance is made for a sixfold increase in weight of the embryos near term, and the amount of phenolsulphonphthalein injected per fetus is increased to 18 mg., there is still an output during a six-hour period of only 20 per cent of the dye from the fetus at the twenty-ninth day. In a study of the permeability of fetal membranes in a series of rabbits observed during the last third of gestation, it was found that following the injection of the gestation sac with 3 mg. of phenolsulphonphthalein per fetus there is an output during a three and two-thirds hour period of about 4 per cent of the dye from the sac at the twenty-first day of pregnancy, while about 40 per cent of the dye is excreted from the sac at the thirtieth day.

**Blood Sugar, Blood Calcium and Blood Coagulability.**—According to Cowan and Wright, the coagulation time of the blood in living animals may be decreased by injections of dextrose. Intravenous injection of dextrose is more effective in decreasing the coagulation time in jaundiced dogs than in normal dogs, not only in the percentage of successes but also in the degree of shortening. Raising the blood sugar through dextrose infusions results in a heightened blood calcium, as well as a heightened blood coagulability. The blood calcium more closely parallels the blood coagulability curve than does the blood sugar curve, after intravenous injection of dextrose. High carbohydrate forced feeding aids the coagulation-time decreasing effect of dextrose injected intravenously in jaundiced animals with liver damage.

**Effect of Methyl, Propyl and Butyl Alcohol on Growth.**—Elhardt describes experiments in which he demonstrated that heavy doses of methyl alcohol injected into the crops of growing chicks had an injurious effect on the growth and vigor as judged from appearance and also the disposition. Abscesses formed in the crop walls of a few of the subjects. Light doses of methyl alcohol had a slight effect on growth but influenced unfavorably the feathering, combs and disposition of the chicks. Heavy doses of propyl alcohol had a markedly injurious effect on growth and a somewhat deleterious one on appearance and disposition. The same was true of light doses of propyl alcohol in a lesser degree. Both light and heavy doses of butyl alcohol did not retard the growth of the chicks or affect the appearance, except that the combs were somewhat anemic.

**Response of Explanted Cardiac Muscle to Thyroxine.**—Markowitz and Yater made a study of the action of thyroxine on cultures of pulsating fragments of heart muscle removed from two-day chick embryos, before the appearance of nerve elements. Thyroxine exerted its typical effect on the frequency of pulsation and contractility of such fragments, bringing about a progressively greater increase in rate, ending in some cases in fibrillation and paralysis. These results constitute evidence that in clinical hyperthyroidism the tachycardia is due to the action of thyroxine directly on the myocardium and not on intervening nerve elements.

Volvulus of Stomach: Report of Two Cases. S. Azmy and A. Marey, Cairo, Egypt.—p. 420.

**Miliary Lung Disease Due to Unknown Cause.**—Sayers and Meriwether describe about 125 cases of typical miliary lung disease as having been found by roentgen examination among 18,000 individuals during routine physical examination. A majority of the patients did not have sufficient symptoms to cause them to stop work or to seek medical aid. The most characteristic observation was a large number of discrete, dense, shotlike spots scattered over the lung areas. Tubercle bacilli were present in only two of the eighty-eight cases in which an examination was made of the sputum. Unstained smears of thirty-one cases (all those examined) were positive for fungus. Two types of fungi were identified—Aspergillus fumigatus-fisheri and Aspergillus niger. Ten cases tested with antigen of Aspergillus fumigatus-fisheri gave negative reactions; six cases tested with Aspergillus niger all gave positive reactions. The authors believe that thirty-eight cases reported by Sutherland as "miliary calcification of the lungs" probably represent the same condition and that these miliary calcifications may be due primarily to fungous infection.

**Mensuration of Heart and Chest.**—According to Fray, readily identified landmarks of the thorax permit the approximate localization of the interventricular septum on the left oblique roentgenogram in most cases. The establishment of this septum permits the recognition of enlargement of either the right or left side of the heart. Working with known material, the author has succeeded in determining the presence or absence of either left or right cardiac enlargement in over three fourths of a series of seventy-three cases.

**Subacute and Chronic Intestinal Intussusception: Roentgenologic Aspect.**—Sussman offers the following as diagnostic criteria in intussusception: (1) obstruction to the passage of barium either given by meal or enema but not often by both; (2) a filling defect at the site of the obstruction; (3) a palpable mass at the site of the obstruction; (4) a change in the position and shape of the filling defect following defecation, and (5) a compression of the adjacent mucosal folds, particularly well seen in the postdefecation roentgenograms.

**Roentgenology of Extra-Alimentary Tumors.**—Gastro-intestinal roentgenologic studies which were made by Wiese and Larimore in 126 cases of extra-alimentary abdominal tumors have been analyzed for the help given to the diagnosis beyond that of disproving the tumor to be from the alimentary tube. The topographic alterations produced in the tract have usually indicated the intraperitoneal or retroperitoneal position of the mass and given strong presumption as to its origin, and in a large percentage of instances have added confirmation to the previous clinical suggestion or have alone supplied the data that indicated the origin of the mass. These observations, together with the clinical data, have allowed a high accuracy to the preoperative diagnosis and have also supplied valuable direction to surgical intervention. The authors believe that these collateral observations to gastro-intestinal roentgenology are valuable in abdominal diagnosis and should be emphasized.

**Therapeutic Abortion Produced by Roentgen Ray.**—Harris states that therapeutic abortion produced by roentgen irradiation offers a method without mortality or morbidity for ending a pregnancy in cases in which surgical intervention is contraindicated and in which future pregnancy cannot be countenanced because of serious and permanent systemic disease. The sterilizing effect of this form of treatment is of special benefit to patients suffering from chronic disease. Partial shielding of the ovaries will prevent amenorrhea in some cases. Of 138 patients treated, complete success was obtained in 129. Three of the six failures showed dead fetuses. The author has had four failures in the last 106 cases. The dosage is 60 per cent of a skin erythema dose into the gravid uterus. The roentgen apparatus must be accurately calibrated, especially for depth dose. There is usually no danger in waiting for expulsion of the fetus if the uterus has stopped growing and if there are no signs of toxic absorption. If failure is discovered before the pregnancy has advanced to sixteen weeks, the treatment may be repeated. If the patient becomes pregnant again at some later date, a second roentgen abortion should be done. The average interval between treatment and expulsion of the fetus is four weeks. The exact mechanism underlying the death of the fetus is not entirely clear. This procedure, when undertaken, demands close cooperation between the gynecologist and the radiotherapist.

**Histologic Grading of Cancers.**—Hueper emphasizes the fact that sections of cancers removed for grading must be taken from the peripheral zone of the tumor and must be properly prepared and stained and evaluated by a pathologist familiar with the method of grading. Grading is helpful in the selection of the type of treatment best suited in the individual case. The grade of malignancy must never interfere with the extent or intensity of treatment. The grade of malignancy indicates the proliferative and metastatic tendencies of a cancer. A reliable prognostication of a cancer must include at least three factors: the grade of malignancy, the extent, and the location of the tumor.

**Results of Operations for Cure of Cancer of Breast.**—Lewis and Rienhoff state that on the basis of their study of the results of operations for the cure of 950 cases of cancer of the breast the conclusion that the large majority of patients with carcinoma of the breast will succumb to this disease is unquestionably warranted. The study establishes the fact that a large number of patients are free from clinical cancer for a varying number of years following operation, but whether or not a patient is ever completely cured (in the pathologic sense) of carcinoma is open to question. Undoubtedly, if operated on properly the condition may be cured locally, and that is the only point for which the surgeon must hold himself responsible. It is, of course, always possible that the disease may still remain a localized process which has not spread beyond the limits of operability, and especially is this so in the very early cases that come under observation today. In view, therefore, of one's inability to foretell the exact limits to which the disease has spread, a thoroughly radical removal should be done in all cases whether early or late. It is a well known and proved fact that patients from whom the primary growth has been removed and who have lived without symptoms of clinical cancer for many years afterward, finally succumbing to some other malady, were found to have regional metastases in which microscopic carcinoma could readily be demonstrated. It would also seem that carcinoma may vary not only in its rate of growth but as well in its damaging clinical effects when the cells are removed from their primary site to a different type of tissue, such as a lymph node or another organ. This idea receives additional support from the observation that the postoperative longevity of patients without local recurrence is greater than of those with a reappearance of the growth in the operative field. This is true despite the fact that in both there may be remote metastases. Hence it follows that, regardless of the extensiveness of the disease, so long as it remains confined within possible operative limits, it is incumbent on the surgeon to perform the most radical and meticulous operative procedure, including a far wider exsection of skin than has been customary, in even the Halsted Thiersch graft procedure as performed in the majority of instances in the past, for it is only by this method that the proper amount of skin and subcutaneous tissue will be sacrificed. There alone exists the possibility of reducing local recurrence to a minimum.

**Results of Treatment of Mammary Carcinoma.**—Adair presents the results of a study of 199 primary operable cases of mammary carcinoma in which complete data for a period of not less than five years are available. On account of the importance of the debilitating diseases other than cancer, which diseases contraindicate radical surgical procedures, special examination is made of those cases in which the patients were treated by irradiation methods. Standard radical mastectomy in the good general hospitals of America yield from 32 to 39 per cent five-year cures. The author's criteria of operability are discussed. Obtaining a "five-year cure" by irradiation methods is accomplished along totally different lines than that by a surgical procedure. The latter is by a wide extirpation of the breast, its contiguous structures and its drainage basin, while the irradiation cures are produced by locking up the local disease in dense fibrous tissue, and starving the disease process by endarteritis, and the direct insult to the cancer cell which is produced by the rays. It is believed that external irradiation alone by radium packs and high voltage roentgen rays is, as a rule, not sufficiently potent therapy to effect cures in mammary cancer. The author considers breast carcinoma to be a relatively radioresistant form of cancer. Most cases of cures by irradiation have been accomplished by the combined interstitial insertion of radium together with external radium packs and high voltage roentgen rays. Of the thirty-seven patients treated by irradiation methods only, four died of intercurrent disease, twenty-one died of cancer, and twelve, or 36.3 per cent, are living over five years. Of the 137 patients treated by the combined irradiation and surgical method, nine died of intercurrent disease, eighty-five died of cancer and fifty-two, or 40.6 per cent, are living over five years. These improved results (40.6 per cent) appear to be due to the added factor of irradiation. On the basis of his observations the author concludes that irradiation, if properly applied, can be relied on to effect a cure in cases of mammary cancer in 36.3 per cent. It offers a substitute weapon but slightly less effective in five-year results than the combination of irradiation and surgery (40.6 per cent). In cases in which surgery is contraindicated, the combined interstitial and external irradiation is the most efficient agent.

**Stereoscopic Roentgenography of Breasts.**—Fray and Warren discuss the differential diagnostic roentgenographic features of mastitis and carcinoma which they have found helpful. They believe that this method imparts information not obtainable by other means known at the present time. Besides its diagnostic value, the method is of definite aid in establishing the prognosis before treatment and subsequent serial roentgenographic study will give important information concerning the response to treatment (as irradiation, and so on). This method is not offered as a substitute for or to replace any portion of the physical or other examination. The physical examination of the breast cannot be too exactingly carried out. The roentgenographic examination should serve, however, as a valuable supplement in establishing both the diagnosis and the prognosis. Most of the gross pathologic changes in the breast are as readily identified in stereoscopic roentgenograms as they are in the gross specimen at biopsy or necropsy. Stereoscopic roentgenograms of the human breast offer many advantages in establishing the diagnosis in suspected cases of malignancy, not obtainable by clinical methods. The earliest changes due to scirrhous carcinoma in the presence of a chronic mastitis are as difficult to identify as they are in the gross specimen. In addition to the diagnostic aid which this method offers, valuable information can be obtained concerning the prognosis before treatment. Serial study is of great importance in following doubtful cases and cases under radiation treatment. Cooperation between the surgeon and the radiologist is essential if the diagnostic accuracy is to be maintained at a high level.

**Gastrectomy.**—Mann and Graham developed a method for the total removal of the stomach of the dog. All gastric tissue was successfully removed from six animals, and they were observed for periods varying from eighteen months to almost six years. Anemia that could be ascribed to loss of gastric tissue did not develop in any of the animals.

**Effect of Arsenic on Rabbits.**—Osborne and his associates note that arsphenamine given to rabbits in therapeutic doses is rapidly metabolized and eliminated, with no evidence of appreciable storage. No appreciable amount of arsenic is found in the parenchyma of the central nervous system of rabbits after the administration of arsphenamine, neoarsphenamine or sulpharsphenamine. Following the administration of therapeutic and lethal doses of tryparsamide to rabbits, the parenchyma of the brain and spinal cord shows appreciable quantities of arsenic. The suprarenals are not storehouses for arsenic. If harm is done, it is due to vascular damage caused during the period of circulation of the unmetabolized arsphenamine. The lack of any appreciable storage of arsenic in any of the organs, except the liver and the organs of excretion, suggests that most of the drug is in the vascular system prior to metabolism in the liver. In comparing the observation following the administration of arsphenamine, neoarsphenamine and sulpharsphenamine, the evidence points to neoarsphenamine as being the least toxic, since it is present in the liver in large quantities at one hour and at twenty-four hours following a lethal dose, and it is being metabolized in sufficient quantities to appear in maximum amount in the organs of excretion. Sulpharsphenamine appears to be the most toxic. At the one hour interval, following a lethal dose, something has occurred to prevent the liver from metabolizing the drug. No sulpharsphenamine appears in the organs of excretion, and little is found in the liver. At the end of twenty-four hours the liver contains a maximum amount of arsenic, but the organs of excretion contain relatively little. In lethal doses, tryparsamide apparently requires little or no metabolizing in the liver but is excreted rapidly by the kidneys and the entire intestinal tract. Over a period of forty-eight hours after the administration of a lethal dose, the liver takes up an increasing amount of arsenic, the amount of which seems to parallel the degree of damage to the liver. A discussion is given of the observation of arsenic in all the layers of the intestinal organs.

**Cheilitis and Stomatitis from S. T. 37 Tooth Paste.**—Templeton and Lunsford report six cases of acute cheilitis following the use of S. T. 37 tooth paste. They could not demonstrate which ingredient was responsible but suspected the altered or unaltered hexylresorcinol S. T. 37.

**Superficial Lymph Nodes in Early Syphilis.**—Michelson examined 145 lymph nodes excised from patients with early untreated syphilis. In approximately 27 per cent of the specimens, tuberculoid structure was present. The test with tuberculin, performed on fourteen patients whose lymph nodes showed tuberculoid structure, was positive seven times. The luotest was negative when performed on nine patients whose lymph nodes showed tuberculoid structure. Tuberculoid reactions found in the lymphatics in early syphilis are variable in type, and apparently the state of allergy is not the same as when this reaction is found in the skin. True gummas of the lymph nodes differ from the tuberculoid structure found in the nodes in early syphilis.

**Persistent Nodules in Scabies.**—Ayres and Anderson state that persistent nodular pruritic lesions which resist the usual sulphur medication may occur as a complication or sequela of scabies. They report five cases in which such a complication occurred. Serial sections of excised nodules in two cases failed to reveal the presence of parasites, ova, larvae or feces. In two cases there was a marked perivascular lymphocytic infiltration of the middle and deep cutis, and in another case there was, in addition, a marked plasma cell infiltration. Electrodesiccation or coagulation followed by curettage seems to be the treatment of choice.

**Unusual Manifestations Following Administration of Gold Compounds.**—Throne and his associates call attention to the fact that all gold compounds are toxic, some more so than others. Their use is attended with danger, but this danger can be minimized by the following procedure: 1. The patient should be examined for focal infections, and one should remove such foci before instituting therapy with gold compounds. 2. A preliminary analysis of the blood should be made: (*a*) a high sugar and low chloride content means a physiologic dysfunction. This should be eliminated by a preliminary course of injections of a freshly prepared solution of sodium thiosulphate. (*b*) In cases showing a high blood sugar content not associated with pancreatic deficiency or metallic retention, the doses of the gold compound should be comparatively small. On the other hand, patients with definite diabetes mellitus seem to tolerate treatment with gold preparations. 3. The first sign of intolerance, as manifested by dryness of the mouth and pruritus, is an indication for discontinuance of the gold compound and the use of sodium thiosulphate. In the authors' experience, these symptoms are invariably accompanied by an increase of the blood sugar, a decrease in the chlorides and frequently a marked decrease in the urea nitrogen. 4. Chemical examination of the blood at weekly intervals, by showing an increase in the sugar and a decrease in the chloride and urea nitrogen content, frequently enable one to foresee an intolerance to gold compounds and, by instituting proper eliminative treatment at once, to prevent reactions. 5. It is impossible to determine previously the tolerated dose for each patient. The initial dose should be small, not exceeding 25 mg. of the gold preparation. This dose can gradually be increased if it is well borne and is not effective, but it should be kept low as long as it shows a beneficial action on the lesions.

## Archives of Pathology, Chicago

**13**: 367-542 (March) 1932

*Secondary Nodules of Lymph Nodes, Their Relation to Chronic Inflammatory Processes. R. E. Miller, Hanover, N. H.—p. 367.
*Experimentally Produced Focal (Dental) Infection in Relation to Cardiac Structure. N. W. Jones and S. J. Newsom, Portland, Ore.—p. 392.
*Experimental Edema and Lipemia Produced by Repeated Bleeding. A. E. Kumpf, Hot Springs, S. D.—p. 415.

**Secondary Nodules of Lymph Nodes.**—General studies of the structure of the secondary nodules of lymphatic tissue were made by Miller on approximately 1,500 lymph nodes removed from 500 cadavers within four hours after death. The ages of the deceased varied from 6 months in utero to 88 years. Nodes were removed from all the regions in many cases; in others, only nodes from a visceral and a peripheral group were taken. Approximately 200 of the nodes were removed from the pyloric region of the stomach. Spleens in all the cases and submucous lymphatic tissue in many of the cases were studied. On the basis of his observations the author concludes that secondary nodules of the active type ("germ centers," the Flemming type of secondary nodule) are rarely found in lymph nodes of man beyond 30 years of age in the absence of long-standing, mild, chronic inflammatory processes. Secondary nodules of the active type are common (98.2 per cent of cases) in lymph nodes associated with chronic ulcerating lesions of the stomach in man beyond 30 years of age. This circumstantial evidence and the histologic picture indicate an etiologic relationship between the pathologic process in the gastric wall and the production of secondary nodules of the active type in the near-by lymph nodes. This evidence is offered in support of the contention that the secondary nodules of lymph nodes arise as the result of pathologic processes. These observations on human material support the conclusion, drawn from experimentation on animals, that the secondary nodules of lymphatic tissue are reaction centers, and should increase the skepticism with which Flemming's hypothesis is viewed.

**Experimental Focal Infection.**—Twelve dogs used in the experiments of Jones and Newsom were subjected to a rigidly followed operative technic, which may be summarized as follows: The dog was anesthetized with ether; the lower canine tooth, or teeth, was isolated with rubber dam and the parts swabbed with iodine. The distal half of the tooth was removed with dental saw and rongeur forceps. The pulp was then removed, the bleeding stopped, and the cavity dried. The cavity was then filled with a streptococcus culture and a pulp point put in place and covered with a small pledget of sterile cotton; a dental cement covering was then placed over the cotton and the tooth permanently filled with silver amalgam. Dental abscesses were demonstrated in all inoculated dogs. There were no other constant extracardiac structural changes. The hearts of inoculated dogs constantly showed very small vegetative or verrucose mitral and (or) aortic endocarditic lesions, patchy parenchymatous degeneration, nuclear changes, increase in the diameter of the muscle cell, and a slight round cell infiltration. A positive relationship between experimentally produced focal dental infection and cardiac hypertrophy as measured by diameters of muscle cells was noted. The authors believe that direct measurement of diameters of cardiac muscle fibers, under their experimental conditions, is a more reliable criterion of cardiac hypertrophy than ratios of heart weight to body weight or of heart weight to body surface area. Stress and strain in the absence of focal infection did not affect the gross or the microscopic characteristics of the heart.

**Experimental Edema and Lipemia.**—Kumpf produced edema in two of four rabbits by prolonged bleeding alone. All rabbits showed a marked and persistent lipemia. The increase in plasma lipoid was primarily in the neutral fat fraction, the sterol fraction as a rule being less increased. Total blood volume and plasma volume fell as the bleeding progressed. This occurred in both the edematous and the nonedematous animals, and was about the same in the two groups. The concentration of total plasma protein fell but slightly; that of the albumin was moderately lowered and that of the globulin at times greatly increased. Reversals of the albumin-globulin ratio were frequently encountered. The edematous rabbits showed a marked edema of the scrotum and anterior abdominal wall, massive ascites and hydrothorax. All edema fluids were high in protein. The urines of all the animals, both edematous and nonedematous, were high in fat. This was mostly neutral fat. There was a variable increase in the lipoid content of the kidney and liver in all instances. In the kidneys of the edematous rabbits there was a striking decrease in sterols, with an equally marked increase in neutral fat.

Physical and Roentgenologic Examination in Diagnosis of Pulmonary Disease. H. S. Willis, Northville, Mich.—p. 224.

**Basophil Adenomas of Pituitary Body.**—Cushing gives the following chronological recapitulation of the facts that have chiefly served to throw light on the subject of basophil adenomas of the pituitary body during the past twenty years: 1. Primary anterior pituitary disorders are commonly produced by adenomas. 2. Adenomas of the endocrine series are as a whole functionally active lesions. 3. Even minute adenomatous tumors of the parathyroids and pancreatic islets may lead to serious constitutional derangements of hypersecretory type. 4. Pituitary adenomas are of three principal varieties—neutrophil, acidophil and basophil, no constitutional disorder heretofore having been definitely ascribed to the last. 5. There is experimental evidence to suggest that the basophilic elements of the anterior pituitary secrete the sex-maturing hormone. 6. A polyglandular syndrome heretofore supposed to be of corticosuprarenal origin, characterized in its full blown state by acute plethoric adiposity, by genital dystrophy, by osteoporosis, by vascular hypertension, and so on, has been found at necropsy in six out of eight instances to be associated with a pituitary adenoma which in the three most carefully studied cases has been definitely shown to be composed of basophilic elements, the lesion in one instance having been clinically predicted before its postmortem verification. While there is every reason to concede that a disorder of somewhat similar aspect may occur in association with pineal, gonadal or suprarenal tumors, the fact that the peculiar polyglandular syndrome described may accompany a basophil adenoma in the absence of any apparent alteration in the suprarenal cortex other than a possible secondary hyperplasia will give pathologists reason in the future to scrutinize more carefully the anterior pituitary for lesions of similar composition.

**Monro-Kellie Hypothesis.**—Weed and Flexner carried out on dogs two series of experiments with records of the pressure of cerebrospinal fluid, of the sagittal venous pressure, and of the carotid arterial pressure. In the first series the cranial dura was widely exposed to the atmosphere, while in the second series the vertebral arches were removed throughout the thoracic and lumbar regions, thus exposing a large extent of the spinal cord directly to atmospheric pressure. With the cranium exposed, the alteration in the pressure of the cerebrospinal fluid, on abrupt tilting from the horizontal to the vertical tail-down position, was considerably less than the pressure alteration in this fluid in the intact animal on such a tilt. When such an animal was tilted from the horizontal to the vertical head-down position, the pressure alteration was of exactly the same magnitude as in the intact animal. In the series with the vertebral canal opened, the pressure changes in the cerebrospinal fluid, on tilting from the horizontal to the vertical tail-down position, were of exactly the same magnitude as in the intact animal. On tilting from the horizontal to the vertical head-down position, the pressure changes were considerably greater than in the intact animal. These experiments are taken to indicate that the intact character of the vertebral and cranial bony system is essential for the adequate protection of the central nervous system against pressure alterations in the cerebrospinal fluid, on tilting from the horizontal to the vertical position.

**Nervous Lesions Following Electrical Shocks.**—Langworthy describes experiments in which he noted that when the current from a 1,000-volt alternating or continuous circuit was allowed to flow through a rat for one second, abnormalities in the nerve cells of the brain or the spinal cord were demonstrated only in areas traversed directly by the current pathway. The electric current produced damage to nerve cells in experiments in which heat production was negligible. If a large current flows through the body for a considerable time, there is marked heat production which causes changes in nerve cells indistinguishable from those produced by the electric current alone.

**Undulant Fever.**—According to Moorehead, undulant (or Malta) fever probably exists in three or more closely related strains, namely: Brucella melitensis, Brucella melitensis-abortus, and Brucella melitensis (porcine). Undulant fever is of world-wide distribution; hence such titles as Malta fever seem inappropriate. Many cases have recently been reported from widely separated parts of the United States. It probably exists in all the states. Wherever searched for carefully, it has been found rather prevalent. Clinically, any patient showing a protracted and unexplained (or partially explained) fever in the face of a negative Widal test should be at once tested for the serologic reactions of undulant fever. There is nothing distinctive about the disease from the diagnostician's standpoint. Unusually mild subjective symptoms with the presence of a high fever, however, seem characteristic. A case of what appears to have been the Brucella abortus variety of undulant fever is reported by the author from the state of Oregon. The disease appears to be disseminated by contact with raw meat of pigs and cattle as well as by the milk of cows and goats. It probably should be classed with tularemia as an occupational hazard, complicating workmen's compensation acts. No specific therapeutic measure is known. Several fatal cases have been reported. Recognition of this as a common disease may clear up the etiology of heretofore obscure mild fevers.

**Massive Collapse of Lung.**—Jones believes that massive collapse of the lung should be made to include all conditions in which a considerable portion of a lung is so compressed as to exclude the air, except those cases in which the compression is being caused by air or fluid in the pleural cavity. It seems probable that spasmodic constriction of the bronchial tubes is the principal causative factor; that bronchial plugging may be the result of collapse rather than the cause of it. This condition should be kept in mind during examinations and roentgen studies of tuberculosis patients. In all cases in which there is extreme dulness in the chest accompanied by increased sound conduction, massive collapse should be eliminated by definitely locating the heart. Extreme contraction of scar tissue is probably the only condition other than massive collapse that will displace the heart to the affected side.

**Injuries to Cartilaginous Structures of Knee.**—According to Lasher, fractures of the fibrocartilage of the knee usually occur under 40 years of age and are invariably due to twisting violence. The diagnosis must be based on the history and examination. Roentgen examination is of little or no value. The clinical picture is clear, unless associated with other joint conditions. Mucoid degeneration of the cartilage and the production of a villous arthritis soon follow injury. Early operation is indicated. A wide exposure is necessary to explore the joint. A mediolateral approach gives the widest exposure. Postoperative immobilization is unnecessary, and, in fact, contraindicated. Postoperative care should include early massage and special exercises. A study of the end-results indicates that 90 per cent of the patients make a complete recovery.

**Treatment of Eczema in Infants by a Milk-Free Diet.**—The experience of Levy and Finkelstein with forty infants placed on a milk-free diet, in which the milk was replaced by a soy bean preparation over a period of from four to nine months, led them to classify thirty-eight infants as improved, two as unimproved. The eczematous condition of the skin began to show marked improvement after from one to two weeks under dietary management and, after observation for periods varying from not less than four months up to nine months, has not recurred. The infants took the soy bean preparation readily. The stools were of good consistency. There were no digestive disturbances. The babies gained satisfactorily. In the authors' experience, the use of a milk-free diet, in which the milk was replaced by a soy bean preparation, has proved valuable as a substantial therapeutic diet in infants with severe eczema.

**Carbon Monoxide and Its Relation to Aircraft.**—White calls attention to the fact that carbon monoxide, a product of incomplete combustion, is present in the exhaust of all types of airplanes. In some types of planes, depending on the type of exhaust leads, fuselage and so on, this gas is carried back to the cockpits of the plane in sufficient concentration to result in as much as 15 per cent saturation of the blood of the pilot and other occupants of the plane. Although the highest saturation of blood obtained during the author's investigation (15 per cent) is not sufficient to render a person unconscious or to be a direct cause of a crash, it is known that the absorption of even minute amounts of carbon monoxide is highly undesirable, owing to the probable adverse effect on the efficiency of the pilot. The fact that exposure to a low concentration over a long period is more harmful than a brief exposure to a very high concentration increases the importance of eliminating all traces of carbon monoxide. Comparatively simple and inexpensive modification of the exhaust leads has eliminated carbon monoxide from the area where it is absorbed by the pilot or other occupants of the plane.

**Renal Calculus.**—Carson submits data on forty-six patients operated on for renal calculus, this group representing fifty-five operations. Spinal anesthesia was the anesthesia of choice and was used with complete satisfaction. Pyelotomy is the operation of choice for kidney stone and lessens the chance of recurrence as compared to nephrotomy. Indications for operation were diminished kidney function, urinary obstruction, infection, persistent hematuria, and pain. Studies of renal function show that when nephrolithotomy is performed in the presence of heavy infection a loss of function with recurrence almost surely follows. There were no deaths following the fifty-five operations for kidney stones.

**Benign Tuberculous Infiltration of Lung.**—Spence reports three cases of benign tuberculous infiltration of the lung (*epituberculosis*). The chief point of interest in these three cases is that clinically they resembled one another, the patients being tuberculous children, each with a massive lesion of the lung which was benign in character and lasted for a year or more, without much disturbance of the general health beyond some pallor and loss of weight in the early stages. In the first two the evidence that the lesion was tuberculous was only presumptive. In favor of this view are the facts that both had positive skin tuberculin reactions and one a history of contact with a tuberculous parent. Any other explanation of the nature of the consolidation is difficult. The children had not had pneumonia, and the complete disappearance of the lesion after it had been present for a year, and the recovery of the lung without signs of fibrosis or bronchiectasis, exclude bronchial obstruction as the cause. In the third case recorded the child was infected at an early age, shortly after birth, so that the failure to gain weight in the first six months of his life had had a more evident effect on his general condition. Otherwise the physical signs of the lesion and the progress resembled those in the first two cases. In the third case the tuberculous nature of the process has been proved beyond doubt by recovery of tubercle bacilli directly from the lung at two sites and on two occasions. The first exploration was made at a point which might conceivably have been the primary tuberculous focus, small in size and central in site. The second exploration was made at a point near the periphery of the consolidated area, as far as possible from the point of the first exploration. Tubercle bacilli were obtained in equal number and with equal facility from the two parts of the lesion. It is clear, therefore, that in this case the infant was infected shortly after birth with a large tuberculous lesion affecting almost the whole of the upper half of the lung, yet causing comparatively little disturbance to his health and no fever, and permitting a gain of weight. The author emphasizes the value of careful examination of material obtained in the syringe needle when exploring the chests in cases of this type. Of the cases described, the chief point of clinical importance is that they demonstrate that even an infant has a great power of recovery from tuberculous lesions of the lung.

**Rickets.**—In a series of 218 outpatient children of Sydney between the ages of 6 months and 2 years, examined for signs of rickets, Maddox found sufficient clinical evidence, according to a specified standard, for a diagnosis of past or present disease in 52 per cent, the higher incidence falling between the ages of 9 to 12 months. Of these children, 129 were examined roentgenologically. Signs of active rickets were found in 12.4 per cent, and of healed rickets in 31 per cent. With seven doubtful cases, the whole roentgen incidence amounted to 50 per cent. On the whole, the infants were well nourished and the disorder was of a mild to moderate degree and of an occult character. Correlation between the clinical and roentgen observations showed that marked rib beading and ligamentous laxity with abdominal and hepatic enlargement were the most frequent clinical signs in a small series of roentgenologically active patients. Symptoms of irritability and spasmophilia were rare; craniotabes and epiphyseal enlargement were notably absent. Apparently only a cautious reliance should be placed on alterations in the size of the fontanel and delay in teething or walking. Dentitional bronchitis is common. Examination of the diets of these children showed that on theoretical grounds evidences of vitamin A and D deficiency could be anticipated in 43 per cent. The diet in forty-one of ninety-six nursing mothers was deemed unsatisfactory from this standpoint. Breast-fed infants provided over a third of the roentgenologically active and a half of the healed cases of rickets. Fresh Sydney milk, which is mostly from the country, seems to have a good protective effect, better at least than insufficient amounts of cod liver oil. The cause of this high incidence among the hospital class is possibly partly attributable to insufficient ultraviolet irradiation, which should correct a dietetic vitamin shortage. Certain suggestions are made toward prophylaxis mainly based on the principle of making positively sure that each infant receives an adequate daily amount of direct sunlight or of ingested vitamin D.

**Lymphocytic Leukemia Causing Pontile Hemorrhage.**—According to Hawksley, the symptoms and signs associated with lymphocytic leukemia are numerous and depend principally on five factors, which may be thus summarized: (1) changes in the circulating blood; (2) pressure from enlargement of lymphoid structures, or from deposits and infiltrations of lymphoid cells; (3) infiltrations of various organs interfering with their functions; (4) hemorrhage, which may be due to blood changes, weakening or infiltration of the vessel walls, and (5) metabolic disturbances not covered by the factors mentioned already, such as pyrexia, and due probably or possibly to the poisonous effects of the disease itself. Such pyrexia will occur with new growths, such as carcinoma and sarcoma, as well as in leukemias. In consideration of the relative commonness of leukemia and the extensive literature on it, it is none the less apparent that involvement of the nervous system is among its rarer manifestations. It is for this reason, and also because of the typical syndrome which was produced, that the author reports a case of hemorrhage following leukemic infiltration of the pons varolii and compares it with other examples of disease of the central nervous system due to leukemia.

**Umbilical Diphtheria.**—Signy and Bruce state that diphtheria occurring apart from the nasopharynx is an unusual occurrence and is frequently fatal, owing to the false membrane not being recognized as diphtheritic in origin. Umbilical diphtheria occurs in the new-born and in infants up to 3 weeks of age. Of the thirty authentic recorded cases, many of the earlier ones were fatal, but in those occurring in more recent times the infants have been treated with antitoxin and have recovered. In a case reported by the authors, diphtheria was not considered in the original diagnosis, the appearance being that of a severe cellulitis with sloughing. The main features to be used as a guide in the diagnosis of umbilical diphtheria would appear to be (1) the well nourished appearance of the child who is sucking well and is putting on weight normally; (2) an inflamed umbilicus with false membrane formation; (3) a normal temperature almost throughout the disease, quite out of proportion to the severity of the umbilical lesion, which, if coccal, should be associated with fever, and (4) confirmation by bacteriologic examination, which should be sought in every infection of the umbilicus, particularly in children during the first month of life. The treatment in these cases is the early administration of serum intramuscularly, to combat the toxemia and prevent the onset of cardiac or neurologic complications.

**Effect of Ammonium Chloride on Metabolism.**—The administration of ammonium chloride by Morris and MacRae to three patients with active rickets and latent tetany, and to one patient with early healing rickets, produced no apparent signs of acidosis. In the tetany-rickets group there was a definite increase in the retention of calcium and phosphorus, a subnormal increase in the output of titratable acid, and a marked retention of the excess chlorine. In healing rickets there was a definite decrease in the retention of calcium and phosphorus, but a retention of the excess chlorine *slightly above normal.*

One patient who was given ammonium chloride over a period of five weeks showed roentgen and metabolic evidence of healing, although the dietetic and environmental conditions were kept unchanged. The observations are discussed and it is concluded that there is no evidence of any tendency to acidosis in rickets.

- Intravenous Urography: Preliminary Observations on Recovery of Iodine as Test of Renal Function Following Injection of Uroselectan. D. P. Cuthbertson and A. Jacobs.—p. 36.

**Uses and Interpretation of Urethrogram.**—Parker believes that urethrography has a definite clinical value in cases of stricture, as, by this method of investigation, the exact situation and extent of the stenosis can be accurately gaged and so the type of operation determined beforehand. Iodized poppyseed oil 40 per cent is the optimum fluid for urethrography because it gives the clearest definition. The sitting position used by the author is the best as a routine in urethrography, as the urethra is projected with almost uniform magnification along its whole length on the plate, and there is in particular no apparent compression of the posterior urethra with urethrograms taken in this position.

**Metastatic Growths of Ureter.**—According to MacKenzie and Ratner, true metastatic growths of the ureters are extremely rare conditions. One should not confuse metastatic growths of the ureter with those resulting from direct extension of tumors of adjacent organs. In metastatic growths of the ureters, malignant cells can always be demonstrated in the perivascular lymphatic spaces or blood vessels about the ureter. A diagnosis of a new growth of the ureter, whether primary or metastatic, is almost always made at operation or in the postmortem room.

- Analysis of One Hundred and Twenty-Six Cases of Malignant Disease of Upper Air Passages Treated During a Period of Ten Years, 1921-1930. L. Colledge and R. Peacock.—p. 161.
- *Vincent's Disease. L. S. Dudgeon.—p. 188.

**Vincent's Angina.**—Dudgeon states that in Vincent's angina the infection may be limited to the gums, which are red, swollen and tender, and which may exude pus at the gingival margin and lead to the formation of single or multiple ulcers, which vary in size. In those cases with considerable tissue reaction a yellowish membrane is formed on the surface of the ulcers, and, if it is detached, bleeding freely occurs. In these cases, gangrene seldom supervenes. Similar ulcers may occur on the tongue, throat or pharynx and present a similar appearance. The ulcers, when situated on the tongue, may be exquisitely tender, and the patients often feel extremely ill. The severity of the illness usually depends on the extent of the infection and the pain associated with the ulceration. The breath is offensive but varies in different cases according to the intensity of the necrosis or gangrene. Some of the worst cases the author has seen of this infection have followed extraction of teeth, especially when there has been much laceration of the gums. There may be evidence of infection around the remaining teeth. In other instances the gums are pallid at the outset and show little or no evidence of tissue reaction, and it is in such cases that gangrene is likely to occur. The tonsils, especially, are likely to be affected, and the infection may extend to the mouth and pharynx. Here, again, as already described in the mouth infections, shallow ulcers may be seen, with a bright red reaction in the walls and covered by a yellow membrane. In the severest cases of Vincent's angina, the ulceration is situated on one or both tonsils and may spread rapidly in various directions; such ulcers are deeply excavated, do not bleed readily, are covered by a purply brownish slough, which is friable, and have a very offensive odor. The margins of these ulcers are pallid, and apparently there is but little reaction. The ulceration may extend deeply into the tissues and severe hemorrhage may occur, especially when there is slight reaction to the infection and rapid extension of the gangrenous process. In these cases of Vincent's angina one sees the severest of all the infective processes which occur in the mouth and throat. As in many other acute infections, the degree of pyrexia is not an indication of the severity of the illness; it may be at a high level for a few days in a simple acute case, or there may be little or no pyrexia. Enlargements of the submaxillary and cervical lymph nodes may be slight or considerable, depending on the severity of the infection, but it seldom reaches the degree encountered in severe diphtheria. The rapidity of the pulse and the degree of toxemia are the surest indications of the severity of the illness. Investigations should be made to exclude any concurrent illness in cases of Vincent's angina.

**Spleen in Streptococcal Infections.**—Orr gives a histologic account of the course of the reaction in the spleen of rats infected with various strains of hemolytic streptococci. The earliest changes are observed in the lymphoid and reticulo-endothelial elements, and those appear to precede any demonstrable infiltration of the spleen with polymorphonuclear leukocytes. The greatest primary activity is found in the perimalpighian zone, at the boundary between the lymphoid follicles and the pulp. Proliferation of reticulum cells with disappearance of lymphocytes is followed by marginal accumulation of neutrophil leukocytes. When the animal dies—in all cases with streptococcal septicemia—focal necroses are found in the perimalpighian region. Subsequent changes in the pulp are congestion, infiltration with polymorphonuclear leukocytes and multiplication of reticulum cells and later of lymphocytes and plasma cells. There is progressive decrease in size of the malpighian bodies. Some of the macrophages may be derived from lymphocytes.

**Natural Immunity to Staphylococcal Toxin.**—Bryce and Burnet state that the distribution according to age of staphylococcal antitoxin in human serum is similar to that obtaining for diphtheria antitoxin. In about 50 per cent of cases, the blood of an infant at birth contains the same concentration of antitoxin as the mother's blood; but gross divergences are not uncommon and point to a considerable lag in the passage of antitoxin across the placenta. Natural staphylococcal antitoxin is frequently present in domestic rats and evidence is presented which indicates that its occurrence is a true response to contact with the specific antigen. The authors believe that the "Dick type" reaction intradermal injection of staphylococcal filtrates in many human beings is not a manifestation of the activity of the staphylococcal toxin.

**Toxicity of Viosterol.**—Duguid and his associates found viosterol to be more toxic to rats fed on a certain synthetic vitamin-free diet, of high calcium content, than to rats fed on a normal diet. The absence of vitamins and the high calcium content were considered as possible agents in determining the toxicity, and the high calcium content was found to be the more powerful of the two. After reduction of the calcium and also the phosphorus content of the diet, some evidence was deduced suggesting that the absence of vitamins also contributed, but this evidence is not accepted as convincing. The toxicity was estimated chiefly on the finding of arterial and renal calcification. The reliability of these lesions as criteria was discussed. Arterial lesions are accepted as reliable indications of poisoning in the rat. Renal lesions were noted to occur in viosterol poisoning in two forms; namely, as calcification of the renal arterioles, and as calcareous cast formations in the renal tubules. The former appeared as part of a general arterial involvement and, as such, was taken as a reliable indication. The latter was found to be a lesion of too common occurrence in the rat, independently of the administration of viosterol, to be admitted as reliable evidence of toxicity.

**Staphylococcal Toxin and Antitoxin.**—According to Parish and Clark, staphylococcus septicemia is a comparatively rare and extremely fatal disease. Toxins of staphylococcus can be prepared in an atmosphere containing 25 per cent carbon dioxide in Parker's 4 per cent peptone buffered broth, on Burnet's 0.8 per cent agar plates, and in Winchester bottles containing 0.8 per cent agar to which Parker's broth is added after forty-eight hours' growth. The toxin kills rabbits, guinea-pigs and mice when given intravenously, produces skin lesions in rabbits and guinea-pigs, and is actively hemolytic. It is rapidly converted into toxoid by formaldehyde. Horse antitoxin can be prepared which protects rabbits against a lethal dose of toxin injected intravenously. It is best titrated by injecting mixtures of toxin and antitoxin intradermally into guinea-pigs, and by testing its antihemolytic power. The antitoxin can be concentrated by ammonium sulphate precipitation. When given intravenously to rabbits prior to a certainly fatal dose of virulent living culture, it prolongs and in some cases saves life. The favorable results that have attended its use in a small number of patients justify more extensive clinical trial.

**Effect of Washing on Resistance of Erythrocytes to Hypotonic Solutions.**—Saslow was unable to confirm the observations of Brinkman and van Dam that washed and untreated rabbit red cells differ in resistance to hypotonic solutions. The resistance of these cells to a given hypotonic solution seems, within limits, independent of the $p_H$, buffering capacity or salt balance of the isotonic washing fluids used to prepare the suspensions for the experiments.

**Rhythmic Contraction of Spleen.**—Experiments described by Barcroft and his associates do not support the view that the spleen has two essentially different rhythms, a specific rhythm with a period of a minute or more, and a Traube-Hering rhythm with a shorter period. The period of the splenic rhythm, shown on plethysmographic tracings, is usually between twenty-five and fifty seconds; but when the spleen is in a bad condition, or the general blood pressure is low, the period of the splenic rhythm is often over sixty seconds.

German Social Insurance and Trade Diseases. H. Betke.—p. 172.

**Hygienic Problems of Reduced Air Pressure.**—Koelsch believes that in estimating the effect on health and the clinical manifestations arising from sojourning in zones where a reduced atmospheric pressure exists, one must bear in mind altitudes and metereological conditions, active or passive ascent, the speed of ascent and descent, and physical and psychic stress. The principal factors in the biologic disturbances are the reduction of the oxygen content and of the oxygen tension, as well as the reduced atmospheric pressure with increasing altitude. Other factors are cold, wind and radiation. As a consequence of these various factors, characteristic ailments, viz., mountain, balloon and airplane sickness, arise. In connection with mountain sickness, which sets in at about 2,000 to 3,000 meters, active ascent is of special importance; however, the modern suspension railways may also be injurious to delicate persons, as the ascent is relatively rapid. Journeys by balloon or dirigible may endanger health, especially in persons previously not perfectly healthy. The greatest biologic strain results from airplane flying, especially at altitudes above 5,000 meters. This strain is indicated by distinct alterations in respiration, activity of the heart, blood pressure, metabolism, and urine secretion. In the central nervous system particularly, far-reaching inhibitory phenomena and defects occur; the eyes and ears may also suffer. It is noteworthy that the static function of man is inadequate to maintain equilibrium, space orientation being chiefly carried out by the eyes; when these cannot function (dense fog, and so on) orientation in space becomes impossible. Airplane sickness proper—denied by some authors—consists in the main of emaciation, disorders of the intestine and the heart, neurasthenic troubles in conjunction with psychic depression and the like; the causes are said to be a chronic deficiency of oxygen in the tissues, excessive strain on the circulation, unsuitable mode of life or inadequate recuperation. Apart from technical safeguards (oxygen appliances, special clothing, and so on), preventive measures chiefly consist in a proper selection of individuals according to their physical and psychic fitness and hygienic mode of life.

**Test for Galactosuria in Icterus.**—Fiessinger and his co-workers describe two tests for determining the passage of monosaccharides through the organism. The amphorotatory test consists in administering a solution of two sugars, one levorotatory, the other dextrorotatory, in proportion such that the mixture is inactive to polarized light. The urine is then tested for polarization; if it is dextrorotatory, the dextrosugar has diffused first, and if levorotatory, the levosugar has diffused most easily. It is found that levulose diffuses better than dextrose, and galactose more easily than levulose. The arteriovenous test consists in the comparative study of the passage of dextrose and galactose. After the administration of 50 Gm. of dextrose or 40 Gm. of galactose, the curve for the sugar of the venous and arterial blood is determined. It is found that tissue retention for galactose is much less than for dextrose. Therefore galactose was chosen as the test substance for hepatic function. For the actual examination, the patient fasts after midnight, voids the urine at 7:45 a. m., and at 8 a. m. ingests 40 Gm. of galactose dissolved in 200 cc. of warm water; he watches his diet for the next twenty-four hours, being careful not to drink more than 1,500 cc. of water. The urine is collected in four portions, at 10 a. m., 12 m., at 6 p. m. and the night urine at 8 a. m. The portions are examined immediately for volume and sugar; the amount of galactose is determined chemically and polarimetrically and a control test is performed by determining the amount of galactosazone. The authors believe there is a relationship between the hepatic cellular lesions, the diuresis and the galactosuria. The diagnosis and the prognosis depend on the concentration and not on the absolute quantity of galactose eliminated. The discussion includes various types of toxic-infectious icterus, lithiasic icterus and neoplastic icterus. Since icterus is due either to retention in the excretory routes or to a fissuration in the trabeculae, the authors explain the phenomena by the notion of trabecular effraction caused by parenchymatous lesions. They also incorporated an index of cleavage (I. C.), which is the ratio of polypeptide nitrogen to total nitrogen, and also an azotemic ratio of urea nitrogen to total nitrogen. The index of cleavage is elevated only in marked glycopexis. The hepatic origin of the disturbance in nitrogen metabolism is more certain when there is an increase in the index of cleavage together with a decrease in the azotemic ratio.

So-Called Roentgen Forms of Pulmonary Tuberculosis. A. Dufourt, J. Angirany and H. Despeignes.—p. 208.

**Roentgen Therapy in Fibromas and Metrorrhagia of Menopause.**—Arcelin undertook research to find a minimum dose of roentgen rays that would arrest menstruation, suppress ovarian function and lead to regression of fibromas of the uterus. He used a tension of 200,000 volts, a Coolidge tube and a filter of 1 mm. of copper and 2 mm. of aluminum. The right and left ventral ovarian regions were irradiated every six days and the rays inclined in such a way that the uterus was irradiated each time. The treatments, in order, were 800 r, 600 r, 400 r and 200 r. At the end of the month, the same ovarian regions were irradiated on the dorsal side and the same series of decreasing irradiations were used. In both series of treatments, while one side was irradiated, the other side was protected by a thick layer of india rubber or lead and the median line for several centimeters did not receive any irradiation. In 95 per cent of the patients treated, the fibroma was reduced and did not give further difficulty. Good results were also obtained in utero-adnexal congestion with hemorrhage in the period of menopause. Roentgen therapy influences the ovarian function rather than the fibroma. Women between 40 and 50 are more usually benefited than younger women. Exact diagnosis should govern treatment: Malignant myomas, necrosing or degenerating fibromas, and calcified fibromas should be left to the surgeon; irradiation is contraindicated in a pregnant uterus or extra-uterine pregnancy; to the surgeon should also be left all lesions such as cysts and tumors of the ovary, salpingitis, pelviperitonitis and in general all inflammatory lesions of the genital tract.

**Acute Hemorrhagic Pancreatitis in Child Aged Five Years.**—Desjacques describes a rare case of acute hemorrhagic pancreatitis in a child aged 5 years. Secondarily there was a necrotic pseudocyst of the head of the pancreas. The author noted an umbilical ecchymosis and a blue sign of the umbilicus, which is a common hemoperitoneal sign. The case reported is a hyperacute pancreatitis since death occurred on the seventeenth day in spite of two interventions.

*Drawing Blood from External Jugular Vein. P. Grellety Bosviel.—p. 356.

**Drawing Blood from External Jugular Vein.**—Grellety Bosviel states that venesection has again been incorporated in treatment, but he believes that it may be performed on the external jugular vein instead of the arm. He discusses three personal observations of asystole: a myocarditis with total cardiac insufficiency and venesection in the external jugular with a bistoury, an acute asystole in the course of pneumonia, an acute edema of the lung and alcoholic hypertension; also two observations, one personal and one from literature, in which there was compression of the superior vena cava. Venesection of the external jugular is indicated when edema renders venesection in the arm difficult and in cerebral disturbances in the course of asystole and compression of the superior vena cava. The author discusses the anatomopathologic factors and the technic in venesection (with a needle or bistoury) from the external jugular vein and concludes that bloodletting from the external jugular vein as practiced in olden times is justified in cases of asystole or compression of the superior vena cava accompanied by cerebral disturbances. In acting directly on the cerebral stasis, the action is more intense and more rapid than that in venesection of the arm.

**Ridiculous Tobacco Advertisements.**—Since the production and marketing of foods and stimulants are regulated by laws, Waser thinks it unusual that for tobacco, probably the most widely used stimulant, Switzerland does not yet have such regulations. He considers it necessary to protect the public against misleading advertisements of some tobacco products. He discusses the efforts of certain institutes to cultivate types of tobacco that either have a low nicotine content or are entirely free from it. After comparing the nicotine content of various tobacco products and discussing the toxicity of nicotine, he shows to what extent the smoking process influences the nicotine and what portion of it enters the organism. He discusses what factors produce the stimulating effect of tobacco, and the influence of nicotine on the nervous system and the circulatory organs. He evaluates various methods that have been recommended to reduce the nicotine content. As most effective he considers the artificial cultivation of types of tobacco that have a small nicotine content or are free from it. He shows that most of the methods that have been recommended to extract the nicotine or to make it harmless are ineffective, for examination of many brands of tobacco products that were advertised as having a reduced nicotine content revealed that they had the usual content or even an increased content. He ridicules and severely criticizes misleading advertisements and demands that these should be curbed by laws to protect the health of the public and also to prevent exploitation by charging exorbitant prices for products that do not fulfil the claims made for them.

*Deviation of Complement in Chronic Gonorrhea of Women. G. Feraco.—p. 137.

**Deviation of Complement in Chronic Gonorrhea of Women.**—Feraco states that many scientists have experimented with the immunity reaction of the blood in individuals with gonorrhea in order to ascertain and control the biologic diagnosis. There are differences of opinion regarding the specificity of the gonorrheal reaction. The majority of investigators, however, take the affirmative stand. The author's research is based on the blood serums of 126 women with chronic gonorrhea of the genitalia. The technic employed, the Wassermann test, revealed a high percentage of positivity. The reaction proved especially valuable for the etiologic diagnosis of cases of chronic adnexal diseases. A control test was made of the blood of forty women who never had gonorrhea or had only a history of previous infection. This revealed a negative reaction in subjects not infected with the gonococcus and in which no gonococcus antibodies existed. The author concludes that: 1. The gonococcus reaction is useful in chronic forms of gonorrhea (91 per cent positive). 2. In practice it is necessary to obtain the proper antigen. 3. The clinician can receive the same assistance from the test for gonorrhea as he receives from other laboratory tests for other diseases.

*Isolated Chronic Torsion of Transverse Colon with Rotation of Stomach. L. Caporale.—p. 183.

**Renal Pseudocalculus from Calcified Echinococcal Cyst.**—Crovery and Placeo point out that the diagnosis of a completely calcified echinococcus cyst of the kidney is especially difficult when hematologic and biologic signs are lacking that indicate a parasitic infestation and when roentgen examination in itself is not sufficient, since, with the complete calcification of the cyst, the peculiar characteristics of such a lesion are absent.

**Hernia of Intestine Through Transverse Mesocolon and Gastrocolic Omentum in Gastro-Enterostomy Patient.**—Pecco emphasizes that in this man, aged 37, there were no symptoms of occlusion but only vague diffuse pains in the abdomen, especially in the epigastrium, arising particularly after meals, and eructations, regurgitation of sour and bitter fluids, and, finally, vomiting, all the disturbances being referable to the stenosis due to the position of the intestinal loops. The symptoms disappeared following intervention, and nine days later the patient's nutrition was without embarrassment.

**Isolated Chronic Torsion of Transverse Colon with Rotation of Stomach.**—Caporale did not find a case of isolated chronic torsion of the transverse colon discussed in the literature. His patient, a woman aged 41, on being admitted to the clinic, was subjected to various examinations to rule out ulcerative or neoplastic lesions of the digestive tract. These, especially the roentgen examination, pointed to anomalies of position, which were confirmed at operation. There being no indications of adhesions, the organs being all in situ, and the intestinal tract presenting a normal development, the author's teacher concluded that a pexy of the colon followed by gastropexy would be the logical intervention. Colopexy was carried out, after detorsion anticlockwise, and sutures were applied between splenic and hepatic angles of the transverse colon and wall of the parietal peritoneum. The stomach was fastened with linen sutures between the gastrocolic juxtapyloric omentum and the parietal peritoneum of the right flap of the laparotomy incision, so as to leave sufficient mobility to the stomach, but preventing it from moving too much. The postoperative course was uneventful.

**Hepatic Tympanism as an Early Symptom of Perforated Gastroduodenal Ulcer.**—In eleven cases of peritonitis due to perforation by gastric or duodenal ulcer, Pieri found, in making the objective examination, in every instance tympanism apparently due to the escape of air from the stomach into the peritoneal cavity through the perforation. The author thinks that this symptom, which is verifiable from the first hours of the perforation, may have a notable clinical value for the early differentiation of acute peritonitis due to perforation of an ulcer from the peritonitis due to appendicitis. In the latter the disappearance of the hepatic dulness is found usually in the terminal stage through the interposition of the meteoric intestine between the liver and the abdominal wall, or through the development of gas due to anaerobes within the peritoneal cavity.

*Gradual Occlusion of Coronary Arteries. G. Cataldi.—p. 152.

**Gradual Occlusion of Coronary Arteries.**—Since the American school has cleared up the syndrome of acute occlusion of a principal branch of a coronary artery, Cataldi has chosen to write on gradual occlusion. The case literature is quite limited. In gradual occlusion of the right coronary, a large collateral circle is established, constituted by anastomosis in the descending branch of the left coronary, the anterior descending branches of the right and correspondingly in the terminal branches of the posterior interventricular branch of the right coronary as well as the terminals of the posterior collateral branch of the left. The most serious myocardial lesions are found in the left ventricle. The increase of the force of systolic contraction and the hypertrophy of the left ventricle produce most intense inhibition of the blood circulation in the myocardium of the left ventricle. Gradual occlusion is more frequent in the right coronary. There are three types of coronary circulation habitually found in: (1) dogs, with a prevalence of the left coronary; (2) equines, with a prevalence of the right coronary; (3) man, with a prevalence of the left coronary. Gradual occlusion is determined either by extrinsic causes by an aortic process, above all a syphilitic aortitis, or by intrinsic causes, and by alterations of the vascular tunics in the initial tract of the coronary. The majority of cases are of extrinsic causation. All authorities agree on the diversity of anastomosis as to size and number. Anastomosis normally exists but cannot maintain a compensatory circulation when a coronary occlusion occurs in the acute stage. If gradual occlusion occurs, capillary and precapillary anastomosis have a greater possibility of development. The territory of the occluded coronary cannot be directly nourished by the blood contained in the cardiac cavity. The author holds that in the alteration of the coronary in its initial tract, either as a myocarditis with or without anginoid phenomena or as angina pectoris without myocarditis, it is impossible to make a diagnosis because (1) one can only suspect the disease and (2) it is useless to think of prognosis and cure.

**Bacterial Content and Disinfection of Tooth Brushes.**—Viefhaus found that newly purchased tooth brushes, whether they have a protective covering or not, are not sterile, for he detected many bacteria, some of them pathogenic. Because of this he considers the sterilization of newly purchased tooth brushes absolutely necessary. Most of the methods that have been recommended for the disinfection of tooth brushes he found to be ineffective, such as sodium chloride even when used in a concentrated form, also formaldehyde vapors that develop at room temperature. However, formaldehyde vapors that are developed under the influence of heat, when potassium permanganate acts on a formaldehyde solution, effect complete sterilization in a comparatively short time. This reliable although somewhat complicated method is not suited for daily use but should be resorted to whenever it is necessary to sterilize tooth brushes of patients with such conditions as alveolar pyorrhea or with parodontitis. It is also suitable for hospitals and sickrooms, and it has the advantage that it does not in the least impair the tooth brush.

Factors Influencing Prognosis of Pneumonia During Childhood. R. Kochmann.—p. 14.
Micromethod for Erythrocyte Sedimentation Reaction. L. Feuerstein.—p. 26.

**Treatment of Acute Encephalitis in Children.**—Kramár and Petrányi discuss treatment with convalescent serum and then cite the case of an infant in which they obtained favorable results with injection of blood from the mother. This induced them to try blood from adults in other cases, but because too large quantities (200 cc.) were required, which might cause complications when injected, they decided to inject only the serum (from 30 to 40 cc.). Of thirty-three children with encephalitis that have been treated by the authors since 1925, twenty were treated according to the usual method (lumbar puncture, quinine, methenamine; iodine preparation and sulphur injections), and thirteen were treated only with large quantities of serum from adults (from 30 to 117 cc.). Of the thirteen who were treated only with serum, two died, whereas of the twenty who were treated according to the older methods, eight died. From this the authors conclude that serum from adults, when given in large quantities, is valuable in the treatment of encephalitis in children. They consider it possible that there are great individual variations in the therapeutic value of the serum of different persons and they think that this may explain their two failures, as well as the fact that in some instances the injection is followed by a sudden improvement, while in other cases the improvement is only gradual. They hope that eventually it will be possible to estimate the therapeutic value of the serums and to be able to select the most effective serum, and even to store effective serum for cases of emergency.

Clinical Manifestations of Glandular Hyperplasia of Endometrium. K. Adler.—p. 340.
Serology of Carcinoma and of Pregnancy Toxicoses: Serologic Pregnancy Reactions. E. Englehart.—p. 349.

**Submammary Elevation of Temperature During Pregnancy and Puerperium.**—On 100 women, in whom during the last four weeks of pregnancy the axillary and the submammary temperatures were determined every day, Bickel observed regularly an increase in the submammary temperature of from 0.1 to 1.2 C. He found that the greater the increase in the submammary temperature during the last weeks of pregnancy, the greater was the milk production during the first seven days of the puerperium. In women in whom the submammary temperature increase averaged less than 0.2 C., the milk production was usually subnormal, whereas in cases in which the temperature increase was more than 0.2 C., the milk production was normal or more than average. The author further states that in evaluating the submammary temperature the shape of the breast has to be considered. If, in case of a pendulous breast, the submammary temperature increase is slight, the probability of hypogalactia is especially great. On the other hand, considerable differences in temperature in case of globular breast indicates a greater milk supply than would the same increase in case of pendulous breast. During the first months of pregnancy, increases in the submammary temperature are observed in only about one third of the cases, and the majority of these women show secretion of colostrum. Examinations in nonpregnant women revealed in 20 per cent of the cases an increase in the submammary temperature. This percentage is small when compared with that of gravidas and puerperas, yet it nevertheless decreases the value of the submammary temperatures for the determination of the secretory capacity of the mamma. If fever exists during the puerperium, a certain reserve is necessary in the evaluation of the submammary temperatures.

Roentgen Treatment of Internal Diseases. F. Salzmann.—p. 387.
Cardiac Action of Calcium. A. Zarcinas.—p. 391.
Hypertension a Chronic Allergic Animal Protein Toxicosis. Bienstock.—p. 397.

**Serology of Syphilis.**—Meinicke shows that research during the last fifteen years has brought the serodiagnosis of syphilis to a high point of efficiency and that it has reached a certain finality. He thinks that differences in the reactions of various tests are only quantitative, that is, relative. If they appear to give contradictory results, this is only because a test is less definite. For practical purposes, that is, as a foundation for diagnosis and as a guide in therapeutic measures, the author recommends the modern precise flocculation reactions.

Therapeutic Measures Advisable in Injuries of Fingers and Hand. E. Gold.—p. 308.

**Acute Articular Rheumatism and Tubercle Bacillemia.**—Reitter and Löwenstein report observations in eighty-two cases of acute polyarthritis. In the majority of cases they were able to demonstrate a tubercle bacillemia, but they consider the mere fact of a simultaneous occurrence of a tubercle bacillemia and of acute polyarthritis as not sufficient proof for a pathogenic connection between the two. However, in addition to the tubercle bacillemia they also found increased vascular permeability and an increased allergy, especially toward tuberculin. On the basis of clinical and bacteriologic observations, the authors conclude that acute rheumatism is an exudative inflammatory phase in the course of a tuberculous reinfection. On the basis of this theory they hope to develop an etiologic therapy. They point out that the treatment with salicylates is neither etiologic nor specific but only an extremely valuable symptomatic treatment. They admit that for the present the salicylates cannot be dispensed with, since they reduce exudation, pains and fever. The disadvantage of the salicylate treatment is that it does not prevent relapses and cardiac complications. As yet the authors do not have a definite therapeutic procedure to offer, but they give suggestions as to what factors have to be considered; namely, to make the tubercle bacilli in the blood harmless, to remove all factors that lead to impairment of the vascular walls (removal of septic foci) and desensitization by means of tuberculin.

**Diathermy Treatment of Ulcer of Leg.**—Because ulcers of the leg, especially varicose ulcers, still represent a therapeutic problem, Szandicz decided to try diathermy treatment. After mentioning various reports that had appeared in the literature about this method, he relates his own experiences. In eleven of sixteen varicose ulcers that had existed many months or even several years, and which had proved refractory to nearly all therapeutic measures, systematic diathermy treatments produced objective results (narrowing of the ulcer or even complete epithelization). However, in three of these cases the healing was only temporary. After medical supervision had ceased for a while, and several weeks after the patients resumed their work, the ulcers opened again. This shows that neither is the therapeutic effect of diathermy always permanent nor does it prevent the formation of new ulcers. In five of sixteen cases, diathermy treatment accomplished nothing: three of these were torpid ulcers with callous margins, one was a crateriform thrombophlebitic ulcer, and one was a varicose ulcer that under the influence of diathermy treatment became erethistic. The diathermy therapy effected improvement in one case of roentgen ulcer and in one case of perforating ulcer of the foot. One ulcer in idiopathic atrophy of the skin was not influenced. In twelve cases of ulcer of the leg the pain was lessened considerably, two remained uninfluenced, and in three cases an estimation was impossible. Five cases of moist dermatitis of the leg, some of which showed infiltrates, were improved in a comparatively short time and some healed completely. One case of artificial thrombophlebitis, in the region of a spontaneous thrombophlebitis that had taken its course, was favorably influenced by diathermy treatment. The author realizes that his material is rather small, but in view of the therapeutic experiences in diffuse inflammations of the skin, he considers his report justified and the treatment deserving of further trials. In evaluating the diathermy treatment for cases of varicose ulcers of the leg the author does not advocate it as the standard method of treatment, for its objective results are not essentially better than can be produced by the usual methods. However, occasionally it may be employed as an adjuvant to other therapeutic measures; for instance, when there is hope that by loosening the marginal portions a stationary process may be made active again, but especially when painfulness disturbs the sleep and impairs the working capacity. Painfulness is counteracted in a large percentage of cases.

**Modification of Growth of Bone by Ferment Action.**—Zawisch-Ossenitz reports animal experiments with an aqueous extract from the growth zones of the bones of calves. That the results obtained with this extract are not due to a nonspecific protein action is proved by the fact that the deproteinized extract had the same effect as the raw extract. The necessary concentration of the extract is done by simply isolating the globulin fraction that contains the largest amounts of the substance. The chemical nature of the extract is not yet definitely known, but certain qualities, especially its thermolability, speak more for a ferment character than for a hormone character. Because the extract is sterilized with tricresol, it is suitable only for subcutaneous and intravenous injection, since intramuscular injection is extremely painful. The author further discusses the dosage and her methods of determining the efficacy of the exact and shows curves that indicate the effects produced by the extract. She further describes the histologic changes in the bones and reaches the conclusion that the administration of the bone ferment containing substance produces bones that are not only quantitatively but also qualitatively superior.

**Influence of Digitalis on Ventricular Complex in Cardiac Insufficiency.**—According to Winternitz, effective digitalis treatments lead frequently but not always to changes in the initial complex and in the final deflection. These changes may be the only manifestation of digitalis treatments that otherwise appear clinically ineffective. The most frequent change in the ventricular complex is a heightening of its deflections. This change is independent of secondary and of extracardial factors and it can be traced to inotropic digitalis action. By it the "low voltage" electrocardiogram can be overcome in a large number of cases, and the outlines of the arborization block become similar to those of the bundle branch block. The low voltage electrocardiogram in patients without edema indicates unfavorable functional conditions of the myocardium. For the prognosis it is important to differentiate between a reversible low voltage electrocardiogram and a nonreversible one. The electrocardiogram of the so-called arborization block indicates the same anatomic changes as bundle branch block. The final deflection in case of a hypertrophic heart is almost as reliable an indicator of the size of the various portions of the heart as the initial complex. Negativity of $T_1$ indicates a pronounced hypertrophy of the left heart, and of $T_3$ a hypertrophy of the right heart, but these aspects indicate neither coronary sclerosis nor degeneration of the myocardium. During decompensation the ventricular complex frequently loses its original outline, which corresponds to the relative sizes of the two sides of the heart, but after digitalis treatment it is frequently restored. Certain characteristics of this process are considered as a proof that digitalis influences primarily the hypertrophic and insufficient portion of the heart. The depression and deformation of the T deflection that is not dependent on the direction of the initial complex is observed in about one fourth of the patients that are treated with normal doses of digitalis. If toxic doses are given, it is more frequent. Intraventricular conduction disturbances develop rarely following digitalis medication, and if they exist before digitalis treatment is begun they generally do not become aggravated, and consequently they are no contraindication to an energetic digitalis therapy. Functional conduction disturbances may improve considerably under the influence of digitalis. Notching and splintering often undergo characteristic changes, which is probably the result of improved conduction. The author reports a case in which by changes in the position of the diaphragm the electrocardiogram of the right bundle block was changed into that of the left bundle block.

**Distribution of Various Sizes of Erythrocytes in Different Types of Anemia.**—Kaemmerer studied the distribution of the various size groups of erythrocytes in fifteen cases of anemia of various origin. He employed the Price-Jones method, and his results corroborate those reported by McCormick, namely, that in secondary anemia the smaller size groups predominate, which consequently reduces the average diameter below the normal, whereas in pernicious anemia there are more large cells or more large and small cells, which has the result that the average diameter is increased. This test method has clinical value in that it may corroborate an otherwise doubtful diagnosis, and also in that it demonstrates the efficacy of an antianemic treatment.

**Free Choice of Foods in Patients with Diabetes Mellitus.**—Induced by Stolte's report (*Med. Klin.* **27**:831 [June 5] 1931; abstr., The Journal, Sept. 5, 1931, p. 748) on favorable results obtained with an unrestricted diet in the treatment of children with diabetes mellitus, Kestermann tried this method in adults. He concludes that a liberal diet is advisable in older diabetic patients, especially when the diabetes is complicated by some other serious disorder; also in younger patients when the food intake is limited because of a febrile disease. He also found that in many severe, chronic, progressive cases of the younger age groups in which insulin treatment is resorted to, a free diet with high carbohydrate and with moderate protein and fat content produces metabolic equilibrium and improves the well being and the general condition much more effectively than a more restricted diet. In cases of medium severity in which insulin injections are given, the free choice of food is likewise advisable since it improves the physical well being and betters the carbohydrate tolerance. The latter factor permits a gradual reduction of the insulin doses. Moreover, the beneficial psychic influence of a free diet should not be underestimated. For the mild cases of diabetes mellitus, however, dietary measures still remain the foundation of the treatment since the inconveniences caused by the dietary restriction are not comparable to those of a continued insulin therapy with several injections daily.

**Diagnosis of Pulmonary Tuberculosis.**—Bernard discusses the clinical consequences of Koch's discovery so far as they concern the symptomatology of pulmonary tuberculosis. He shows that although the presence of tubercle bacilli in the sputum is the only scientific proof for the nature of the process, it cannot always be practically utilized, for it is inconstant. The elimination of bacilli in the sputum may be sparse, it may be intermittent and it may even be absent in patients who actually have tuberculosis. This shows that the diagnosis cannot be based only on the elimination of bacilli in the sputum. But, on the other hand, bacilli should be carefully searched for, and, if they are not found, the diagnosis pulmonary tuberculosis should be made only if several other factors indicate its existence and other conditions can be excluded. Yet even if the practical significance of Koch's discovery for the estimation of the tuberculous sputum has been somewhat limited, it remains evident that his discovery has been the source of an inestimable progress, not only in that it added to the knowledge about tuberculosis, but also by making a more precise diagnosis possible, which in turn is valuable for prophylaxis and therapy.

**Tubercle Bacillus and Invisible Elements of Tuberculosis Virus.**—Calmette shows that modern methods make it possible to observe the development of the filtrable elements of the tuberculosis virus to the fully developed tubercle bacillus, but he also shows that there are certain gaps in this knowledge that have to be filled by further investigations. It is the task of the clinicians to differentiate between the disease producing action of the ultravirus and that of the tubercle bacillus. The author believes that many infections in which a few acid-fast bacilli but no tubercles are found, namely, such conditions as erythema nodosum, purpura rheumatica, and certain skin diseases that are accompanied by serous or articular effusions (pleurisy, pericarditis, meningitis and so on), are probably caused by the filtrable elements of the tuberculosis virus, and he suggests that all these conditions be grouped together as "prebacillary granulemias." The group of true bacillosis would then include only the generalized or localized diseases in which formation of tubercles takes place and which generally take a much slower course. The classic example of this category is chronic pulmonary tuberculosis. In the conclusion the author pays tribute to Robert Koch, who with his discovery of the tubercle bacillus opened this wide field of investigation.

**Evaluation of Tuberculin.**—Küster and Strempel describe an intracutaneous method for testing tuberculin. By making the test on three series of animals, an exact evaluation is possible. The main purpose of the test is to detect those tuberculin preparations that are most suitable for cutaneous and for intracutaneous use. The method is based on the simultaneous, qualitative and quantitative observation of all reaction manifestations twenty-four, forty-eight and seventy-two hours after intracutaneous injection. The tuberculin preparation that is to be tested is compared with the standard tuberculin on the same animal.

Partially Calcified Ductus Deferentes. H. Hofer and H. Lossen.—p. 153.
*Critical Evaluation of Direct Filling of Urinary Passages with Contrast Medium and Experiences with New Medium (a Thorium Dioxide Preparation). E. Meyer.—p. 157.
Urology of Children in Whom Cystoscopy Is Impossible. E. Ruge.—p. 171.
*Simple Method .for Localization of Suppuration in Urinary Tract. R. Roth.—p. 182.

**Filling of Urinary Passages with New Contrast Medium.**—After differentiating between positive and negative contrast mediums, Meyer discusses the necessary qualities of the positive contrast mediums and shows to what extent the various mediums meet these requirements. He then describes his experiences with a thorium dioxide preparation, which he employed in 200 cases. He considers this preparation the most suitable positive contrast medium for the ureters and the renal pelvis. It absorbs more roentgen rays than do sodium iodide and lithium iodide in the same concentration, and it can therefore be used in a lesser concentration. For the mucous membrane it is indifferent and painless, and if it enters the blood stream it is relatively nonpoisonous. If it is retained in a cystic kidney even for several weeks, there are no reactions. It mixes readily with the urine contained in the organs and thus makes the organs readily visible. It does not flake out and consequently does not lead to obstruction. It only has the disadvantage of a certain viscosity, but this can be overcome by a suitable technic. Of the negative contrast mediums the author prefers oxygen, which, when it enters the blood stream, causes less disturbances than air. To the question whether positive or negative contrast mediums are preferable the author does not answer directly but states that if size, shape and outlines of the hollow organs are to be visualized, only the positive contrast mediums are suitable. If the filling of the cavity is done for the purpose of demonstrating a foreign body that has the same absorption coefficient for roentgen rays as have the surrounding tissues, and consequently gives no shadow, a positive or a negative contrast medium may be advisable, depending on the difference in size between the foreign body and the surrounding hollow organ. If the calculus is in a narrow space, a positive medium is advisable. However, filling with oxygen is preferable if a calculus is in a comparatively wide hollow organ and also for the demonstration of adenomas of the prostate.

**Simple Method for Localization of Suppuration in Urinary Tract.**—Roth states that whereas the two-glass test and the three-glass test indicate only whether the pus contained in the urine comes from the urethra, the bladder or the prostate, he employs a method that reveals whether the pus comes from the upper urinary passages or whether these passages are free from pus. He has the patient evacuate the bladder into two or three glass receptacles. If these urine specimens do not indicate definitely the origin of the pus, the bladder is irrigated with sterile water until the irrigating fluid is clear. Then the bladder is completely evacuated. After that the opening of the catheter is closed for several minutes, until sufficient urine has collected for a new examination, after which the catheter is removed. If this last portion of urine is clear, that is, if it does not contain pus, it can be concluded with certainty that the specimen of urine containing the pus does not come from the upper urinary tract, but if the last portion of urine does contain pus, the source of the pus must be in the upper urinary passages.

### Zentralblatt für Chirurgie, Leipzig

*Severe Swine Erysipelas in Human Beings. H. Domrich.—p. 593.
Appendicitis as Secondary Disease in Carcinoma. F. O. Mayer.—p. 597.

**Anatomic Localization and Treatment of Painful Shoulder.**—Dollinger shows that the cause of painful shoulder, a condition that has been referred to erroneously as periarthritis humero-scapularis, as chronic subacromial bursitis or as subdeltoid bursitis, is not an inflammation of the bursa but rather an inflammatory infiltration, a muscular hardness, of the supraspinatus which is caused by overexertion. Because of the deep, protected position of the supraspinatus, the author employs a special method of examination. With the four fingers pressed together, he exerts a strong pressure on the muscle and thus intensifies the pain. As a control examination he exerts the same pressure on the same region of the other shoulder but here produces only the feeling of pressure. In six cases that came under the author's observation it was the supraspinatus that was painful, but in one of them the deltoid muscle was likewise involved. After the pain has been localized, massage of the painful muscle is begun in order to effect resorption of the exudate. Usually the pain in the shoulder is considerably reduced after the first treatment. The stiffness of the shoulder requires longer mechanical treatment, but brisement forcé exacerbates the condition. Since the trouble is of purely local nature, internal treatment is superfluous.

**Severe Swine Erysipelas in Human Beings.**—Domrich, after reviewing the literature on swine erysipelas in human beings, describes the clinical history of a woman, aged 24, who, while working on foods, cut her finger slightly. Subsequently the finger became red and a few days later all the other fingers of the same hand became involved. Several weeks later the hand and the lower part of the arm showed bluish discoloration, and light red areas appeared on the upper arm. There also was considerable exfoliation of the skin. Erysipeloid was thought of, but treatments with ointment bandages, blood injections, quartz lamp irradiation and painting with iodine proved ineffective. The patient had fever, and the red discoloration spread over larger areas of the body. Injections of calcium and of sulphur did not check the further spread of the disease. Bacteriologic examination of the patient's skin revealed the presence of typical erysipelas bacilli; however, the blood was free from these bacilli. Erysipelas serum was now administered, and the fever and the cutaneous manifestations disappeared promptly. When after several days the fever increased again the serum injection was repeated, but this time it was followed by a severe anaphylactic shock, which subsided again in two days. After six days there was another attack of fever, and an exanthem developed around the cutaneous wheal. However, this lasted only several hours. Signs of impairment of the cardiac valves were not detectable. This and the absence of erysipelas bacilli from the blood show that this case of erysipelas was not like the septic endocarditis of swine. In the summary the author emphasizes that this form of erysipelas of human beings has not been described before. It is characterized by a disease of the skin which develops in successive crops over the entire body, also by toxic impairment of the cutaneous capillaries, which leads to bluish discoloration of the skin and finally by septic temperatures that are higher in the morning than in the evening. Serotherapy is the only effective treatment for this form.

### Polska Gazeta Lekarska, Lwów

**11:** 173-192 (March 6) 1932

*Etiology of Influenza (C'cn). M. Gieszczykiewicz.—p. 173.
*Arrest, or Change of Symptoms of Shock in Blood Transfusion, by Previous Impregnation of Red Blood Cells of Different Type. M. Gedroyć.—p. 175.
Hydrogen Ion Concentration on Surface of Skin. (C'td.). J. Stopczański.—p. 180.
*Sex Hormones and Their Therapeutic Application. L. Gerhardt.—p. 183.

**Etiology of Influenza.**—With regard to the rôle of Bacillus influenzae in influenza there are two hypotheses: 1. Pfeiffer described it as specific. 2. Scott, Strümpell, Donaldson and others attributed to it only secondary infections in influenza. Gieszczykiewicz states that the second hypothesis is nearer the truth because it explains without additional suppositions the known facts. To explain the prevailing absence of the influenza bacilli at the beginning of a pandemic, Pfeiffer's theory requires additional hypothetic interpretations. Aphanozoon coryzae and Enigmoplasma influenzae are discarded as exciting causes of influenza by recent investigations on the etiology of this disease. Bacterium pneumosintes is known to be a semisaprophytic micro-organism, frequent in normal flora of the respiratory organs. Thus, concludes the author, the etiology of influenza remains unknown.

**Arrest of Shock in Blood Transfusion by Previous Impregnation of Red Blood Cells of Different Type.**—In previous research, Gedroyć demonstrated that autogenous blood may be changed by impregnation into a different type. He then reversed the experiments and found that also a different type of blood, after proper impregnation, may become similar. The method used was as follows: Erythrocytes from fresh defibrinated blood were washed from five to eight times in order to remove traces of serum and hemolyzed by distilled water in the proportion 1:5 or 1:10. Next, the hemolyzate was rendered isotonic and then cleaned by centrifugation. To this hemolyzate erythrocytes from the donor's blood were added and impregnated at room temperature or in an incubator at 37 to 38 C., for one hour. Epinephrine at times was added in a 1:25,000 or 1:40,000 solution, as an index of eventual hemolytic processes. After impregnation, the erythrocytes were washed several times, mixed with physiologic solution of sodium chloride and injected intravenously, from 0.5 to 5 cc. per kilogram of animal body weight. The first series of experiments showed that heterogenic erythrocytes (which when transfused cause symptoms of shock, fall of blood pressure, noncoagulability and leukopenia), after impregnation with autogenous hemolyzate, change their group character in such a way that the transfusion does not cause shock or fall of blood pressure. The second experimental series demonstrated that, in cases in which transfusion of isogenic and heterogenic erythrocytes did not cause shock, the impregnation of these erythrocytes with the recipient's own hemolyzate changed their character in such a manner that they provoked marked symptoms of shock. The author remarks that, in contradiction to the prevailing belief, the hemolytic processes alone do not cause symptoms of shock after the transfusion of blood. He concludes that by proper selection and proper impregnation of morphologic elements of a donor's blood it becomes possible to foresee occurrence or inhibition of shock and its character.

**Sex Hormones and Their Therapeutic Application.**—According to Gerhardt, since Zondek's investigations two kinds of female sex hormones have become established: (1) those of the ovary and (2) hormones of the anterior pituitary lobe. The ovary produces two hormones, folliculin and lutein. The anterior pituitary lobe produces four hormones: prolan A, prolan B, the hormone of growth, and the hormone influencing metabolism. Of the latter only prolan A and prolan B are related to the organs of regeneration. Thus there are four female sex hormones: folliculin, lutein, prolan A and prolan B. Folliculin, chemically, is probably an oxyketone. It was obtained in crystalline form first by Doisy and Butenand. It is produced by the cells of the stratum granulosum and of the theca interna folliculi in the ovarian follicles, during the first sixteen to eighteen days of the menstrual cycle. By its action the uterus and its mucosa thicken. This action involves also the ovaries; when folliculin is introduced from without, small doses stimulate and large doses depress them. Lutein was obtained in pure form by Corner in 1929. It is produced by the yellow cells of the corpus luteum from the sixteenth or eighteenth day of the menstrual cycle until two or three days before menstruation. Lutein causes reduction in thickening of the uterus and its mucosa, with menstruation as a result. It also exerts an inhibitory action on the growth of the graafian follicles. Prolan A and prolan B are antagonistic in their action on the ovaries. Prolan A causes maturation of follicles, ovulation and secretion of folliculin. Prolan B changes the graafian follicle into a corpus luteum and causes production of lutein. From the described mechanism of hormonic action follows the therapeutic application of hormones. In his clinic the author uses, with great caution, the hormonic therapy in all functional diseases of the ovary. To stimulate the ovaries prolan is given intramuscularly, from 100 to 200 units daily, for from ten to twelve days, combined usually with folliculin. When inhibitory action is desired, as in excessive hemorrhages from the uterus, or for the purpose of hormonic sterilization, prolan is given in larger doses, intravenously and for a considerably longer time. Lutein is also used for inhibitory action on ovaries. Folliculin in doses not over 500 units stimulates; in larger doses it depresses. The author administers prolan and folliculin in amenorrhea and scanty menses, and lutein and large doses of folliculin in excessive menstruation. He warns against the indiscriminate use of hormonic therapy and adds that, so far, good results have been reported in menopausal disturbances treated with folliculin.

Faults in Benzidine Microtest of W. C. Stadie and E. C. Ross. V. M. Kipyan.—p. 476.

**Movement of Cerebrospinal Fluid in Central Canal.**—Ulyanov reports further studies on movement of cerebrospinal fluid in dogs injected with dialyzed india ink. Injections were made into the fourth ventricle of six dogs. In three the ink penetrated only into the central canal, collected in the pelvicocentral portion, and was absent in the ventricles; in two instances it penetrated into the central canal as well as into the ventricles, and in one instance it penetrated into the ventricles only. Injection into the subarachnoid spaces of five dogs proved that the penetration was only in the region of the neck and sometimes the thorax; it never reached the pelvis; there were small quantities throughout the central canal, especially in the caudal portion. The lymphatic vessels in the region of the nerves of the tail and the lymph nodes between the vertebrae of this region were in all cases filled with ink. The author concludes that these and other experiments that he has made prove that the fluid in the cerebrospinal central canal normally moves in the caudal direction.

**Scarlet Fever with Primary Metastasis in Lungs.**—Savrimovich cites three instances of scarlet fever in children who died from the fourth to the seventh day of the disease and in whom, aside from the exanthem, the primary manifestation was a necrosis in the lungs and bronchial lymph nodes, while changes were not observed in the throat or tonsils. The clinical facts point to a rapid localization in the lungs. The microscopic changes are discussed in detail.

*Antidiuretic Activity of Pituitary Extract Introduced into Stomach. S. I. Ordinskiy.—p. 610.
Reversible Hemolysis. V. A. Belitser.—p. 618.

**Hemorrhage from Vessels of Neck During Scarlet Fever.**—Shtein discusses fifteen personal observations of hemorrhage from the blood vessels of the neck during scarlet fever and concludes that hemorrhage in scarlet fever is not frequent. A diffuse phlegmon originates in the suppurating lymph nodes and then spreads to the blood vessels in contact with the abscessed regions. More of the hemorrhages are arterial (ten instances) than venous (five instances). There is a close relationship between the hemorrhage and the abscess: hemorrhage from a deep temporal artery was related to cervical abscesses; abscesses in the subcutaneous tissue caused hemorrhage from either the temporal artery (one instance) or the external maxillary artery (two instances); other hemorrhages from vessels in proximity to abscesses were noted from the common carotid (two instances), internal jugular vein (three instances), anterior jugular vein (two instances) external carotid artery, superior laryngeal artery, and the ascending palatine artery. Hemorrhage occurred not earlier than the fourteenth day of the disease and not later than the thirty-fourth day. In half of the patients, death occurred several minutes after the onset of the arterial hemorrhage; in the other half a small hemorrhage was followed after several hours by another and fatal hemorrhage. Venous hemorrhage was not as serious and occurred several times in one day. Death usually occurred several hours after the venous hemorrhage had ceased. The author describes four types of changes in the walls of the blood vessels studied histologically: (1) a necrosis of the wall of the vessel and the surrounding tissue due to a fusospirochetal gangrene, (2) necrosis due to both streptococci and Bacillus fusiformis, (3) superficial necrosis due to streptococci alone, and (4) a displacement of the vascular wall by granulation tissue. The pathologic changes vary from diffuse necrosis to the development of granulation tissue, with changes involving leukocytic infiltration intermediate between the two. In most of the cases studied the streptococcus was found alone or associated with a bacillus (in one case Pfeiffer's bacillus).

**Antidiuretic Activity of Pituitary Extract.**—Ordinskiy studied the water exchange in dogs with chronic fistula in the urinary bladder; these dogs received 250 cc. of distilled water and either subcutaneous injections of concentrated solutions of pituitary or intra-intestinal administrations of pills of pituitary alone or together with the water. The pituitary preparations were made in accordance with the international bureau of pharmaceutic standards. The pills in some instances were covered with phenyl salicylate. The author concludes that powdered pituitary in pills covered with phenyl salicylate is antidiuretic in doses of from 0.5 to 3 mg. (0.47 to 2.82 international units) per kilogram of body weight in the dog. The action begins the second or third hour after its introduction into the stomach. This dose is from thirty to fifty times larger than the dose injected subcutaneously. The antidiuretic effect is not due to the histamine present in the pills, since histamine salts in doses of 2 mg. per kilogram of body weight did not inhibit diuresis. The observations in the case of a man (the author himself) who received from 10 to 15 mg. in pills not covered with phenyl salicylate showed some antidiuretic action from the pituitary extract. The author believes that pituitary extract in pills covered with phenyl salicylate could be utilized in the treatment of diabetes insipidus.

*Features of Modern Surgery of Sympatheticus. E. Platou.—p. 225.
*Respiratory Paralysis as Only Symptom of Paralysis of Acute Poliomyelitis. Y. Ustvedt.—p. 251.
*Colony Types in Dysentery Bacilli Type III and Different Relations to Normal, Active Serum. T. Thjøtta and E. Waaler.—p. 258.
*Preparation and Storing of Bacterial Antigens, Particularly Gonococcus Antigen, by Drying. T. Thjøtta and E. Waaler —p. 275.
*Value of Sedimentation Reaction in Dermatovenereology. P. L. Rotnes. —p. 280.

**Features of Modern Surgery of Sympatheticus.**—Platou says that in spastic conditions in which Stoffel's operation is ineffective he has obtained such good results by gangliectomy according to Royle and Hunter that further application of the method is justified. Of his eleven cases of sympathectomy, with fourteen operations, five were instances of Little's disease.

**Respiratory Paralysis as Only Symptom of Paralysis in Acute Poliomyelitis.**—In three cases observed by Ustvedt in 1929, a respiratory paralysis with rapidly fatal outcome developed after sudden onset of fever, without establishment of other paralysis. In the fourth case reported, fully resembling the first three, the diagnosis of acute poliomyelitis was verified at necropsy. The fifth case, regarded as an encephalitis, was at necropsy found to be an acute poliomyelitis; while there was no difficulty in respiration during the course of the disease, the sudden death is attributed to a respiratory paralysis.

**Colony Types in Dysentery Bacilli Type III and Different Relations to Normal, Active Serum.**—Thjøtta and Waaler found both smooth and rough colonies in primary cultures from the stools of patients with dysentery due to dysentery bacillus type III. They say that the S type soon dissociates into the R Type, which is stable and found in all old cultures of this micro-organism. The S and R types present the characteristics described as typical for these variants in other bacilli. Further, the R type is sensitive to the action of normal serum and in bactericidal tests rapidly dissolves, while the S type is resistant to the serum.

**Preparation of Gonococcus Antigen.**—Thjøtta and Waaler prepare the gonococcal antigen for application in the complement fixation test in gonorrhea by drying the emulsions in an exsiccator; they then store it in the dry condition. The appropriate dose is fixed by titration before the drying. To use, they emulsify the antigen by adding distilled water until the original volume is restored, and add the saline solution required for the necessary concentration. Large quantities can thus be prepared at a time, and stored without danger of spontaneous inhibition. Dysentery and typhoid antigens have also been successfully treated by them in this way.

**Value of Sedimentation Reaction in Dermatovenereology.**—In his review of the relation of this reaction in venereal diseases and the most important dermatologic disorders, Rotnes shows that while the reaction does not play a significant part in dermatovenereology it may occasionally be of help both in differential diagnosis and in therapy and prognosis.

*Ovarian Cycle Hormone, Folliculin, with Especial Regard to Conditions of Resorption and Elimination. T. Kemp and K. Pedersen-Bjergaard. —p. 215.
*Administration of Parathyroid Hormone in "Infiltrations" of Subcutaneous Tissue and Muscles. O. Horn.—p. 221.
*Conception of "Subcutaneous Infiltrations." H. Jansen.—p. 228.
Case of Exceedingly Grave Exophthalmic Goiter with Roentgen Treatment. T. Eiken.—p. 233.

**Ovarian Cycle Hormone, Folliculin.**—Kemp and Pedersen-Bjergaard compared the investigations of others on the fate of folliculin in the organism with their own observations. They conclude that the resorption of folliculin, even after the administration of large doses, is probably fairly complete and rapid from the intestinal canal, only small quantities (in their tests, about 6 per cent) being eliminated in the urine and still less in the feces; only when the folliculin content of the blood is extremely high, as in pregnancy, is there a large elimination in the urine, somewhat less being eliminated in the feces. The resorbed folliculin circulating in the blood is destroyed relatively fast; if there is regular administration over a longer period of time the elimination is therefore slight, while the specific effect is greater. The comparatively pure folliculin preparations are presumably resorbed rapidly from the alimentary canal and thus are less effective than less pure preparations, and the use of many small doses is more effective than the application of a few larger doses. In hormone analysis, determination of the folliculin content of the urine affords only incomplete information on the relation in the blood, and examination of the hormone content of the feces is as a rule unnecessary.

**Administration of Parathyroid Hormone in "Infiltrations" of Subcutaneous Tissue.**—Horn asserts that subcutaneous injections of the parathyroid hormone has a favorable effect on the so-called infiltrations of the subcutaneous tissue (subcutaneous fibrositis, cellulitis) and the frequently concomitant myalgias. In many but not all cases a peculiar euphoria was noted, which must be regarded as a specific effect of the hormone. Scattered orientating laboratory investigations on the total blood calcium, diffusible blood calcium, sedimentation reaction, total blood protein, blood picture, osmotic resistance and blood phosphate in patients with infiltrations failed to give certain evidence of pathologic changes.

**Conception of "Subcutaneous Infiltrations."**—Jansen says that the diagnosis of "Subcutaneous infiltrations" is made only when there is tenderness in the subcutis. The cause of this tenderness is a neurasthenic condition. He objects, for practical reasons, to the term "subcutaneous infiltration" and "cellulitis" and prefers "adiposalgia." His statements do not concern pathologic connective tissue nodules that may be found in the subcutis.

# THE FAMILY DOCTOR AND PIONEER PHYSICIAN OF THE WEST

## CHAIRMAN'S ADDRESS

G. GILL RICHARDS, M.D.
SALT LAKE CITY

As one's memory wanders back to earlier years, the first question likely to present itself is, what influence created one's desire to study medicine? The particular impulse or deciding factor in the life of each of us has probably been different. I wonder, however, if many of us, especially the older ones, cannot look back on pleasant contacts in our late boyhood days with some fine character in the medical profession whose influence largely molded our decision.

It has always been a source of great pleasure to me to have lived just early enough to have been intimately acquainted with some of the group of early medical men who typify the fast disappearing family doctor. It is of him and his immediate predecessor, the pioneer physician of the West, that I have chosen to speak.

Probably the pioneer physician of the West was not much different from the same character in the East, but the West is still comparatively young, and the inspiring and unselfish lives of such men still linger in our memories. They lived under conditions so vastly different from those now prevailing that I feel it a duty to stir your recollections of their type in the hope that the memory of their real reactions on the life of their day may still influence the lives of future medical men, as they have both those of the present and those of the immediate past.

Such recitals as Dr. Pusey's life of his father in the seventies and eighties should be an inspiration to every young medical man. I dare say that many who have read it felt the same kindred feeling as I, that it could easily have been the life history of one's own father.

I have always been grateful that my early experience belonged to the horse and buggy days, because it makes me feel that I had at least a touch of the life of the country or pioneer physician. It helps one to appreciate what they accomplished and the great handicaps under which they practiced compared with today.

The early medical men who played their part in the pioneering of the West came to the particular locality where they settled, either because of some religious conviction or because they were caught up by the gold rush or were brought by the spirit of adventure. Later, as the news of the wonderful western climatic conditions spread, some came seeking better health.

As one reads Dr. Henry Harris's "Story of California Medicine," from which I have here borrowed freely, or the life of the early medical men in the pioneer days of Colorado, Utah and other Western states, one is impressed with the generally high character of the early pioneer physician. True, there were a few medically minded bandits and impostors, but fortunately they lived only a brief life in our medical history.

I cannot believe that many of our early medical men moved West because of failure elsewhere, which seems to have been the case in many instances in recent years. The majority of our pioneer physicians were well educated, cultured, and in many instances, men of rather exceptional medical training. Not a few had spent one or two years in European clinics and brought to the new West the most modern of medical practices.

As one reads Dr. Harris's biographic sketch of such men as Gibbons, Cole, Toland, Cooper and Lane, one realizes that medical progress in the wild and exciting West was from the first destined to be rapid and on a high standard. The establishment of hospitals, inadequate though the first ones were, the foundation of medical societies and schools, the interchange of opinions and the publication of reports and treatises on medical problems were some of the accomplishments of these energetic and progressive professional men in the early fifties and sixties.

Medical men of the early West were not solely concerned with health problems but showed keen interest and participated in educational and civic development. Many were leaders in politics, and some edited the first newspapers. This was not only the case in California but also in the intermountain states. Dr. Willard Richards, my grandfather, was the first editor of the *Deseret News* in Salt Lake City in 1850. Dr. John M. Bernbisel was Utah's first representative to Congress in 1853. Dr. William F. Anderson, a well trained army surgeon who came West during the Mexican War, settled in Yolo County, California, in 1849. After several years of practice there during those wild days of gold rush history, he migrated back to Salt Lake in 1857 where, as recorded in his journal, "He hoped he might practice medicine among his peers in a more civilized and law abiding community." Dr. Anderson's life typifies that of many of our pioneer doctors, in that he held many positions of civic as well as of professional responsibility, besides taking care of an active practice over a large area of sparsely settled country. He was the president of the first medical society in Utah in 1870.

Many personal incidents as examples of the kindly feeling of the earlier medical men to the recent graduate are told in the sketches of the lives of these men. They were not jealous of the recent and rapidly progressive

---

Read before the Section on Practice of Medicine at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

type of medical training which younger men brought home with them. Even such radical teaching as Pasteur's germ theory of disease and Lister's antiseptic surgery were quickly accepted by many. Others, more stubborn and prejudiced, refrained for years from acknowledging the truth of such revolutionary theories. Belittling young new comers to the laity was of rare occurrence. The experience of the older physicians easily dovetailed with the better training of the younger ones and often resulted in partnerships beneficial to both. One could truthfully say that Ross' motto, "No doctor's reputation gives him the privilege of being careless of the young doctor's rights," typified this relationship. Consultations were common, were usually initiated by the doctor and were held with much dignity and formality.

Medical ethics was rigidly observed. Any attempt at unethical advertisement was severely criticized. Seldom does one see in medical announcements of today the dignity of California's first medical announcement on Nov. 3, 1847, which read, "Dr. Fourgeaud has the honor to offer his professional services to the citizens of San Francisco and vicinity, Office at Jones Hotel."

The instruction given to students in the early days of California's first medical schools was usually sound, and some excerpts should interest us today. For example, Dr. Toland, in his address to a graduating class in 1865, stressed the advisability of service and courtesy to the poor: "Some who were poor a few years back are rich now and do not forget those who ministered to them when they were in distress."

Robert Louis Stevenson showed his appreciation of the services of a pioneer physician, Dr. William Bamford, to whom he sent a copy of his "Travels With a Donkey," inscribing in it this tribute:

> You doctors have a serious responsibility. You call a man from the gates of death, you give health and strength once more to use or abuse. But for your kindness and skill, this would have been my last book and now I am in hopes that it will be neither my last nor my best.

The medical profession was confronted in our early history with their responsibilities toward the social problems of their respective communities. It was apparently just as difficult then as now to obtain a united opinion from the medical group. The doctors, therefore, lacked the unity necessary to obtain favorable legislation in health and sanitation. It is recorded, however, to their credit, that they depended much more on education than on legislation for the control of social ills. The abuse of alcohol and attempted legislation to control its use early demanded the attention of the medical profession. Temperance societies were formed as early as 1850, and the therapeutic value of alcohol in medicine was a very live question.

Laws governing prostitution and making it a crime to disseminate information leading to abortion were social problems of interest to the doctors as well as to the laity in the late fifties.

One of the difficult problems in early medical practice was that of transportation. Little can we picture in our days of efficient travel the difficulties encountered in pioneer days, especially before the advent of the railroad. The highways were never good, and in certain seasons they were often next to impassable with any kind of vehicle. Distances that had to be covered were great and weather conditions often anything but pleasant. The surest means of reaching one's destination was frequently on horseback. I doubt whether those pioneers would have agreed with Henry Morse Stevens who once said, "Transportation is Civilization."

These trips, especially in the mountain districts, did not permit the cultivation of such diversions as those enjoyed by Dr. Francis Adams, the famous doctor and scholar of Aberdeen, who read much Greek and Latin as he made his daily rounds on the back of his horse. It usually required a doctor's undivided attention as he rode to keep warm, and in certain districts it was necessary to keep an eye open for attacks by bandits or Indians. It is interesting to note in this connection, however, that a doctor captured by either of these groups seldom suffered bodily harm. Medical men held a peculiar and privileged relationship to the bandit element, which frequently indulged in shooting and knifing affrays. Because the services of a doctor were often necessary, the usual haunts and hiding places of these gentry were made known to him, and no shrewd bandit ever knowingly molested him. The medical men enjoyed a relative immunity from the usual holdups. A Dr. Eichelroth of early California records a common dialogue:

Bandit: Hands up and hold 'em high.
Doctor: What the hell do you want of me?
Bandit: Oh, it's you, Doc? Go ahead.

The type of practice followed by all the pioneer physicians was necessarily general. In the early days most of the obstetrics was performed by midwives, who called for the doctor's assistance only when complications arose. It was generally taught and practiced by the better trained physicians that meddlesome interference in obstetrics was dangerous, and that in most cases, if left alone, delivery would occur successfully.

In medicine they were called on to treat almost the same group of diseases as seen today, except for those that have almost disappeared—thanks to modern medicine. In early California, when mining was almost the sole industry, diseases resulting from food deficiencies were common. Cholera also invaded early California at rather frequent intervals. These diseases were seldom encountered in the inland states where agriculture was the main pursuit. Respiratory diseases were common in the winter months and gastro-intestinal infections in the summer. Contagious diseases reaped a heavy toll, particularly among the children.

Sudden deaths are often mentioned but usually attributed to apoplexy or heart failure. Angina pectoris or coronary thrombosis may have been the cause of some of these deaths, but all reference to them is lacking.

There is no account of any of the diseases later described as indigenous to the West, such as Rocky Mountain spotted fever. The history of the Mormon pioneers relates many cases of mountain fever, which, however, do not fit the picture of spotted fever.

Apparently there existed in the early days, as now, those doctors who gave much medicine and those whose observations enabled them to select the drugs which had proved of most value in their treatment of various symptoms and diseases.

Early surgery consisted almost entirely of the traumatic type. Shooting and knifing were altogether too common and were responsible for much of the emergency surgery. Amputations of limbs were often necessary as results of common accidents. History records the exceptional skill which these early men developed in this particular line of surgery. The surgeon's kit of those days, containing his saw and a series of amputation knives, is probably familiar to all of you. What a fertile culture medium the beautiful plush lining of those kits must have been. In the preaseptic days, the only concern in the care of instruments was to prevent rust and protect the edge of the knives. Fractures occurred frequently and were generally handled with great confidence except when compounded. This type usually became infected and was a common indication for an amputation. I dare say that the stories of their usual good results in dealing with the simple fractures, as I have heard some of the older men relate with pride, could partly be accounted for by the absence of roentgenograms.

When the happy day of anesthetics came, chloroform was the one usually employed, and it is remarkable how few accidents occurred from its use until a later period when it was used for long operations.

The carbolic spray must have been a vicious thing when used promiscuously. Some terrible sloughs and scars resulted from its use.

I recently enjoyed an afternoon listening to the delightful reminiscences of Dr. Driver, who is still practicing in Ogden, Utah, at the age of 84. He is a man whose vocabulary is sufficiently picturesque to paint a very vivid picture of many of his early experiences, which apparently typified the routine life of the early medical men. He showed me a prescription book which he prizes very highly. In it, he has copies of the ordinary prescriptions for almost every disease and symptom commonly encountered in his practice since the early seventies. As was the custom then, he compounded and dispensed most of his medicines.

He related a bit of philosophy, which he thinks has helped him out of many difficult positions: "Common sense means good sense, and most successful medical therapy is common sense."

A habit of his that probably saved many of his patients from infections in the days before the value of asepsis or antiseptics was known was the care he used in washing his hands with soap and water, followed by alcohol as a means of washing off the alkali of the soap.

I was interested in his use of water glass and a bandage before the days of adhesive plaster, without which we feel today we can hardly keep house.

The majority of the earlier medical men in frontier life did not allow the question of diagnosis to weigh too heavily on their consciences. Their laboratory methods and physical equipment, on which we of today rely, possibly too largely, were almost nil. Necessity made them keen observers, and their own mental faculties were rather alert. I think generally there was seldom much doubt in their own minds as to what ailed their patients. Since their therapy was largely symptomatic and seldom specific, the finer differential diagnosis probably made little change in the outcome of a case.

I feel quite certain that the modern medical man, in spite of his better training through which he is able to save more lives, is not held in the same almost exalted esteem as was the pioneer doctor, nor does he enjoy quite the same love and affection of the families he serves. Even the early doctor's dress and the dignity with which he carried himself were characteristic and inspired confidence. He prided himself on the type of horse and carriage he drove, which usually distinguished him in his community. In the early days it was almost as easy to pick out the doctor of a community as it was the preacher or the sheriff. His opinion was not as likely to be questioned by his patients as it is today. His visit to the home of the sick was considered an event and was often shared by most of the nearby friends and relatives.

I have had some of my older patients say to me, "It was your father's visits and not his medicines that did us so much good; and you younger men never seem to have time for that."

Recently I received a letter from Dr. Stoddard, now living at Spanish Fork, Utah, and enjoying good health at 83. In speaking of his impressions of his long medical career, he writes:

> One cannot live so close to the hearts, the inner lives, the joys and sorrows of a people as I did for several generations, if he be worth his salt, without making for himself a warm place in their affections.

This pioneer physician has been a keen observer and a constant student and has watched with great interest the medical development in the last sixty years. He recalls very vividly some of the trying experiences of his earlier years when he felt keenly the loss of some patient, whose life he realizes now could easily have been saved by the skill of our modern young doctor, with the help of our up-to-date hospital. He wonders, however, just what this same well trained young doctor of today would have done had he been called on to meet the same emergency out in the "wild country," as he refers to it. He pleads for tolerance in the minds of the young before they pass judgment on the older practitioners. This venerable old man feels that our modern medical training and elaborate equipment may fail to develop in the doctor of today an independence and resourcefulness on which the earlier men without modern facilities had to rely.

Let us hope that our high degree of medical training and specialization may not spoil our young men by making of them merely additional cogs in the wheels of modern medicine in this present machine age, but rather that modern methods and physical equipment may be valuable adjuncts to a well trained medical mind, which can still be just as resourceful, as self reliant and as humane as was that of the medical man of pioneer days.

May I, in conclusion, draw for you a word picture of this fine old character, the pioneer family doctor? More often than not he was middle-aged or elderly. Book learning beyond that of most of his fellow pioneers had not puffed him up with vain glory but had made him tolerant and kindly; and experience in healing not only the bodies but the souls of the members of his sparsely settled community had made him wise and resourceful in service and counsel. In manner, he was grave but cheerful. His eyes were keen and observant but always kindly, and on occasion could twinkle most contagiously, and now and then, in stress of the sadness of others, which he made his own, could brighten with unshed tears. His manner was often brusque, but his hands were always gentle, though he knew only too well that swift pain was often most merciful. His dress was occasionally rough and coarse, but clean and neat. His big gold, hunting-case watch with its massive chain was almost a badge of his profession and a quieting wonder to the ailing child who sat on his knee and forgot the pain in the delight of hearing the cheerful tick-tick-tick and watching the revolutions of the busy second hand.

But it was in times of life or death crisis that the old family doctor was at his best. Then he became general and army all in one. He literally took off his coat, detached his cuffs, rolled up his sleeves and assumed command not only of the patient but of the sick-room and the whole terrified family. There were no nurses to carry out his orders. He made up his mind what to do and did it, if it took all the rest of the night and all the next day as well. His day's work was as long as pain and suffering called. His charity was as broad as the wide territory he served. He loved children and the faithful horse that carried him on his rounds of mercy. There was a man who *practiced* his ideals of service, under conditions never easy and comfortable and sometimes barren and grim to the extreme, and yet kept faith with himself and his people. A homely hero he was—nothing less.

# PREVENTIVE MEDICINE IN GENERAL MEDICAL PRACTICE

ROGER I. LEE, M.D.
BOSTON

A good doctor thinks primarily of his patient, and with this the patient is enthusiastically in accord. This traditional attitude of the practicing physician has made the doctor an intense individualist. It has made the doctor the partisan champion of the welfare of his patient against all opposing interests. It has inspired the confidence, affection and admiration of patients for their doctor. I trust no one would change the substance of this relation between doctor and patient. It is important to note that this feeling is entirely personal, and many patients who are devoted to their own doctors may often be quite cold to the medical profession, to organized medicine and to abstract mass medical procedures which we usually call public health measures. Likewise, many doctors are to a considerable extent cold to any procedure that modifies in any way this personal relation between them and their patients. Hence it has naturally followed that doctors have often been instinctively and unconsciously unsympathetic with such annoying bookkeeping details as the registration of births, the reporting of certain diseases, the accurate recording of the causes of death, etc. Perhaps partly for this reason another type of medical man has frequently been introduced to do this work. This type of medical man is mass-minded rather than individual or patient minded. This type of man can think in terms of a pure water supply, remote from the individual patient, and is keenly interested in safeguarding other foods and drinks and in controlling sewage, industrial hazards and the like. He gets satisfaction and comfort from statistics, rather than from the case of Mr. Smith. This is the familiar and older type of public health official—sometimes in the past a versatile man who was also a good practitioner, but nowadays, by the drift of general agreement, a somewhat specialized type of medical man and perhaps not always a doctor of medicine.

But this is only a small part of the present view of preventive medicine. The general practitioner of all time has always been concerned with the personal preventive side of medicine. In that he has had the complete cooperation of the patient. Very little has been written about this until recently, and there has been no established technic. It has been one of those things that has long existed, but has only recently come into the field of consciousness. Consequently it is frequently hailed as a new discovery. But just as physicians have practiced psychotherapy since the beginning of time and long before the word was invented, so doctors and the laity have understood certain causative connections, for example, between green apples and stomach ache, in which there were preventive possibilities. Indeed, if one wished to be subtle and delve into psychology and symbolism, one could go back to the preventive possibilities that are to be recognized of the earliest recorded and most famous apple.

The idea has slowly been developing that it is in this field of the intensely personal relation of doctor and patient that offers the best fruits of endeavors for preventive medicine. The feats of public health in the mass are now accomplished achievements, and they have been great. But the prevention of the present great scourges, such as degenerative heart disease, arteriosclerosis and nervous instability, lies apparently largely in individual hygiene. With the present knowledge and equipment, the prevention of venereal disease and of most infections of the upper respiratory tract, the control of cancer, etc., depend largely on the personal attitude of the individual patient. This personal attitude of the patient is best developed by the continuous close relation of doctor and patient. Doubtless many lay people learn much from reading, lectures, radio talks and the like. But not infrequently this so-called education needs control and testing in personal interviews between patient and doctor.

The general practitioner and his somewhat showy, perhaps more imposing but also less substantial, brother, the internist, is nowadays frequently consulted for apprehension in regard to heart disease or again indigestion, to use common examples. The activating impulse may be an annual examination, the death or illness of a friend or relative or so-called public health publicity. The old family doctor knew the family and past history and the habits and constitution of the patients and could start at that point. The present general practitioner may or may not have that advantage. Often, now, the general practitioner and nearly always the internist must dig out these data. The actual examination may be a small part, but it must be adequate. If the earlier details of the family history, past history, habits and constitution are neglected, the examination must be much more extensive and yet may be misleading. And furthermore, in such an event the opportunity for constructive personal preventive measures is lost. Likewise, it must be pointed out that in a large clinic, either private or public, this preventive medical aspect may easily be lost. The segmental scrutiny of the patient has its disadvantages in this respect.

The laity is prepared to accept the idea of personal preventive medicine with enthusiasm. Patients no longer feel that they must wait for obvious and marked incapacity before seeking medical service.

The personal preventive measures have already been considerably developed in certain specialties. The dental specialty has been keenly alive to these possibilities, and while it is passing through an experimental era in regard to many of the details of preventive dental medicine and while perhaps there is not yet sufficient grasp and indeed sufficient data regarding some of the more fundamental aspects of preventive dental medicine, nevertheless, the general idea of preventive work in dentistry has been accepted with enthusiasm by the public.

---

Read before the joint meeting of the Section on Practice of Medicine and the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

At the present time the large emphasis in the practice of pediatrics is preventive in the same personal sense. The parents employ a pediatrician (or a general practitioner as the case may be, but the highest development is usually seen in pediatric practice) shortly after the birth of the child, and the pediatrician regulates the food and every other habit of a well baby. He makes routine physical examinations of the well baby, and then of the well child. Furthermore, the pediatrician or family physician performs vaccination against smallpox, arranges for diphtheria and other immunization, etc. The careful pediatrician or family physician is the one who refers the baby or child to the dentist, oculist and, if necessary, to the nose, throat and ear specialist. In addition, the pediatrician or family physician helps in the decision in regard to school, outside activities and the like. The mother who was carefully observed during her pregnancy is quite prepared for this.

And yet grown men and women are not as a general rule receiving the supervision and guidance that are in any way comparable to those received by babies and children. The schools and colleges are now beginning to take up in a somewhat mass fashion the preventive work begun by the pediatricians and general practitioners among the babies and children. Curiously enough, students in medical schools have been, at least until recently, allowed to be unhygienic to a shocking degree, with disastrous results, most notably, perhaps, in regard to tuberculosis. The example of personal preventive medicine in the group of medical students is, of course, the best education for future physicians in preventive medicine.

It is true that many medical men already do such work to a varying degree. But a more acute consciousness on the part of doctors of the preventive side of practice is needed. And perhaps of more importance is the collection of data dealing with normal physiology and psychology, as, for example, a knowledge of the effect of exercise on healthy persons as well as on patients with cardiac disease, on convalescents or on the orthopedic patient, and a knowledge of dietetics, not only for obese or undernourished patients, patients with gastric ulcer, costive patients or diabetic patients, but also for the maintenance and betterment of health. Within a generation the importance of focal infections as the underlying cause of varying systemic disturbances has been established. We are now on the threshold of the elucidation of the relation of perhaps symptomless physiologic disturbances of the gastrointestinal system to health. Again researches in the realm of endocrinology offer ground for the belief that the future may furnish the necessary data and equipment to make life better and fuller even if life may or may not be prolonged.

Thus far disease has been studied backward from the autopsy table and from the well developed and essentially incurable stage. The beginnings of disease ought to be studied, since in that stage many diseases may possibly be entirely cured, and thus the chronic manifestations of these diseases may be prevented. In any event, in the early stages of disease one is nearer the actual causes, and if cure is impossible, nevertheless, the abdominal condition may be controlled to the extent that life is not shortened and normal activity during life is not seriously limited. There are many instances of this, of which I shall just call to your attention one, arthritis, in its manifold varieties.

It is, then, in this field of personal or private living and environment that one looks to see the advances of preventive medicine, and here the general practice of medicine must play an important part. It must from its knowledge, investigations and experiments give more information concerning the effect of the various habits and environments on the maintenance and betterment of health. It must put into the actual practice of medicine all this information. Personally, I feel that this is the duty and prerogative not of another specialist, but of the general practitioner or internist. Just as the occasional superspecialist in heart disease, blood disease, diabetes or gastric ulcer may be useful, perhaps an occasional specialist in exercise, dietetics, recreation and the like may be advantageous, but I trust they will not be many. I believe that the general practitioner or internist is entirely competent to deal with this most important aspect of preventive medicine.

Of course, adjustments will have to be made which will involve changes in the methods of medical practice. I believe that these changes will generally tend to benefit the doctor professionally and materially. There will be always the inevitable and disturbing emergency sick calls of many kinds. But the substitution of orderly preventive work under good conditions for much of the harassing hectic sick calls under unfavorable conditions will lead to greater medical effectiveness and higher professional standards with less physical and nervous drain on the doctor and with, I trust, more adequate remuneration. I believe that the start already made shows that the public, now receptive, will be really enthusiastic and will be as appreciative of the preventive art as it is of the healing art.

# PRESENT-DAY TRENDS OF PRIVATE PRACTICE IN THE UNITED STATES

MORRIS FISHBEIN, M.D.
CHICAGO

Consider the practitioner of medicine in 1875. His complete equipment, in most instances, consisted of his five senses developed to extraordinary degree, and such medicaments as he could carry in his saddle bags. In the diagnosis of disease he took, first of all, a history. Since the time of Hippocrates, great practitioners have recognized the importance of a knowledge of the natural history of disease or the course that a disease usually follows. After taking a suitable history, he proceeded to confirm his diagnosis by physical observations. The temperature was estimated by placing the hand on portions of the patient that seemed to be hot. By sight the doctor tried to tell the difference between a blush and a fever. He gazed on the tongue. The eruptions associated with various exanthems were to him an open book. Even the sense of smell was employed, and many a disciple of Aesculapius gambled on his ability to diagnose diphtheria or typhoid with his nose alone. The odds in that day were far easier than at present. Then it was safe to say that one case in five was typhoid; today the disease has been so largely eliminated as to constitute a curiosity, viewed with amazement by medical students. The sense of touch and the sense of hearing were main reliances. Palpa-

Read before the joint meeting of the Section on Practice of Medicine and the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

tion, percussion and auscultation were the three gods of physical diagnosis.

Then came the great shift from brains to glassware. Away from the bedside and into the laboratory turned the center of interest. Every secretion and excretion of the human body became the subject of weird chemical manipulations which yielded astounding information. The practitioner sat with his eye glued to the ocular of the microscope, searching for casts, counting red and white blood cells, studying mitoses, and delighting in strange crystalline conformations.

Next came the roentgen ray, and the unseen was made visible. The old time practioner might hear the râles; the modern practitioner sees the cause of the râles. Not only were the x-rays in themselves to constitute a valuable source of exact knowledge, but soon advances in technic enhanced their usefulness. The Graham test enables visualization of the gallbladder; the use of iopax permits gross changes in the kidney to become apparent; by the injection of air, the brain, the spinal cord and the contents of the abdomen are outlined with the x-rays.

Before the coming of the modern era, the physician had no way of knowing exactly the ability of organs to function. When it began to be realized that the body is a great physical-chemical mechanism in which reactions constantly go on, means were developed for measuring these reactions and thereby for determining functional efficiency. Moreover, actions involving motion within the body are translated into scrolls visible to the naked eye. Thus medicine has by application of inventions in mechanics and electricity progressed more and more into a science. The microscope, the stethoscope, the ophthalmoscope and all the other scopes associated with various organs project the human eye into dark and impenetrable cavities. The sphygmograph, plethysmograph and electrocardiograph bring the heart beat on a screen, determine the nature of its action, and indicate means for restoration of disordered function. Not all of these great contributions to the science of medicine have come from the clinic. The minute physiologic investigations on the frog, the ameba, the dog and the cat have been translated into procedures applied to human beings for the prevention, the diagnosis and the treatment of disease.

### THE RISE OF SPECIALIZATION

Thus the five physical senses of the old time practitioner have been prolonged, projected and intensified thousands if not millions of times. But common sense has been little changed—and may have decreased. Knowledge has accumulated so vastly that no longer is it within the compass of one man to learn and to apply all the knowledge or the technical procedures that are available. The physician of an earlier day has evolved into the multiple specialties of the present. The specialties themselves have been divided and subdivided into technicalities beyond the comprehension of the man in the street. For example, the first of the divisions was the removal of diseases of the eye, ear, nose and throat into a specialty. Shortly thereafter, ophthalmology and otorhinolaryngology became separate specialties. Gradually a few otologists discontinued laryngology and rhinology and began to concern themselves solely with the ear. Moreover, some of the laryngologists began to confine themselves largely to bronchoscopy or peroral endoscopy.

Indeed, the most remarkable examples of fission have taken place in what was formerly called surgery. The first splitting that occurred resulted in general and abdominal surgery; then came gynecology. Thereafter general surgeons began to limit themselves to the head, to industrial surgery and to intrathoracic surgery, and the ultimate result of these repeated parthenogeneses is not yet in sight.

In 1925 the American Medical Directory listed 15,000 specialists; by 1928 the number had increased to 19,000; today there are 160,000 physicians in the United States, and at least 40,000 are specialists. In 1915, 30 per cent of all graduates became specialists; by 1920, 51 per cent of graduates were becoming specialists; today three fourths of the young men undertaking medical education have chosen their specialties before the senior year.

### THE GROWTH OF THE HOSPITALS

It became apparent, just as soon as the practice of medicine began to require great expenditures for accessories and equipment, that individual physicians could not in most instances supply themselves with all the necessary space and apparatus to carry on the multiple activities of modern medicine. Furthermore, the earlier equipment was such that it could not be readily transported to the patient's bedside. Of course, this fact in itself was a great stimulus to American inventors. Today the cumbersome x-ray machines, electrocardiographic devices and basal metabolic apparatus of an earlier day have been developed into portable machines that can be carried to the patient's bedside. But in 1905 it was necessary to place the apparatus in an institution and to bring the patient to the machine. This condition helped toward the tremendous increase in the number of hospitals. From 1900 to 1930 the number of hospitals in the United States increased from over 1,000 to more than 7,000; the number of beds in these hospitals increased from 421,065 in 1900 to 950,000 in 1930. At the same time, attempts were made to overcome the cost of staying in a hospital by the development of x-ray and clinical laboratories which undertake diagnostic procedures. By 1920 there were 3,000 clinical laboratories in the United States, and by 1930 the number had increased to more than 4,000.

The hospitals first built were frequently merely places providing beds and the minimum amount of laboratory service. Gradually hospitals began to provide complete x-ray departments, clinical laboratories and physical therapy services. By 1920 there were 2,500 x-ray departments in hospitals, and by 1930 more than 5,000. Today more than 75 per cent of hospitals are properly equipped with x-ray departments and clinical laboratories.

Another significant factor during this period has been the entrance into medicine of suitable nursing service. In 1890, 400 nurses graduated from available nurse's training schools. In 1930, 20,000 nurses graduated from such schools, and it is estimated that, if conditions continue with the same type of education and training that existed in the past, 65,000 nurses will graduate in 1950.

The coming of the hospital into medical practice, while adding greatly to the cost of medical care, has vastly improved the quality of the care. Medical service can never be judged by price; it can only be judged by quality. Inefficient medical service is expensive at any price and leads only to further expense.

### THE NATURE OF DISEASE

The Commission on Medical Education just a few years ago made a survey of the nature of medical practice in a typical New England community. It was found that 90 per cent of disease was seen and treated by the general practitioner. Of the patients seen, 55 per cent were attended in their homes, 35 per cent in the physician's office and 10 per cent in the hospital. Of the 160,000 physicians in the United States, more than 100,000 have today an affiliation with a hospital. Even though they may not be members of the staff, they have access to the use of the operating room, x-ray department, clinical laboratory and hospital beds. It must be constantly borne in mind, however, that 90 per cent of all disease seen by physicians represents the type of disease that any good general practitioner can diagnose suitably and treat suitably with the amount of equipment that he can carry in a handbag. It is the remaining 10 per cent of disease that gives serious concern to the sociologists, the economists, the philosophers, the philanthropists and all of those who in recent years have participated in the discussions of the cost of medical care.

The coughs, the colds, the minor digestive disturbances, the occasional rheumatic twinges, headaches, the minor gynecologic and most obstetric procedures come within the purview of suitable control by the general practitioner. Such cases as tumor of the brain, acute hemorrhagic pancreatitis, hypertrophy of the prostate or Raynaud's disease may demand consultation with specialists or their technical services. Any good general practitioner ought to be able to outline suitable artificial feeding for most babies in health and in disease. A pediatrician may be required for celiac disease or pyloric stenosis. The otorhinolaryngologist may offer to the patient with a vasomotor rhinitis comfort beyond what the general practitioner may give him, the allergist may seek more successfully the cause of hypersensitivity which turns out to be a reaction to leopard's dandruff, and the psychoanalyst may extract more efficiently the psychosis underlying a cardiospasm. But the vast majority of wage earners are too busy in these modern times attempting to provide their families with the $10 necessary each week to feed a family of five to develop any of these exceedingly interesting but after all quite extraordinary complaints. To the wage earner who is attempting, with his family, to subsist on $30 a week, a pain in the epigastrium is just cramps and not allergic abdominal migraine.

### THE QUALITY OF MEDICAL CARE

Hardly a decade has passed since one of our great sociologists initiated the circulation of the striking statement that the rich and the poor received the best medical care, and that our great middle class is not receiving satisfactory medical service for a price that it can afford to pay. All of us will agree that good medical service is essential to human happiness and that therefore good medical service should be available to all human beings for what they can afford to pay. But good medical care differs greatly from the best medical care. In view of the advances of modern medical science, it is questionable whether or not the best medical care can ever be furnished to all the people at a price they can afford to pay. It would seem rather that we must work toward the period when all of mankind in this country will receive the best medical care that they can be furnished for what they can afford to pay. Thus, the person who seeks transportation to New York travels by bus, by day-coach, by pullman, and in the pullman he has a lower, an upper, a compartment or a drawing room, according to what he can afford to pay. He may indeed choose rather to make the trip by airplane. No economist has suggested, however, that drawing rooms be provided for all who care to make the trip at a fixed price. Indeed, it is rumored that even in Soviet Russia, under the five year plan, there are varying prices for those who wish to sleep en route as contrasted with those who seek to torture themselves through the night on the hard seats of the coaches.

### EXPERIMENTS IN MEDICAL PRACTICE

In response to the demand for the finer refinements of medical science applied to the 10 per cent of serious diseases that has been mentioned, the hospitals, the x-ray departments and the clinical laboratories began to function. Then came some of the experiments already in effect for distributing the cost of these refinements over a considerable number of patients, and thereby lowering the expense to the individual. These experiments have involved the development of groups, such as the Mayo Clinic, and several hundred replicas thereof on a smaller scale, throughout the country. The desire to utilize such refinements caused the organization of commercial clinical laboratories, which provide laboratory service at fixed fees, sometimes the laboratories being the property of physicians and, in other instances, owned by business men who employ physicians to carry out the work. The American Medical Association has wisely refused to recognize on its approved list any laboratory not under the direction of a reputable physician.

Coincidental with the advancement in medical science came the expansion of the curriculum of the medical school, the raising of requirements for admission, and the demand for hospital internship subsequent to medical education. With these requirements it became impossible to conduct a medical school as a profit making venture or without endowment. Increasingly medical educators went to the state or to great philanthropies in search of funds to meet the deficits. Since a sufficient number of beds for teaching purposes is essential to a well conducted medical school, hospitals were built as portions of medical schools. These hospitals were conducted at first as part of the service to the poor, which medicine has ever rendered uncomplainingly and without payment.

As has been shown, the increased cost of medical care began to be reflected in the daily cost of hospital beds. This cost increased gradually from $1.25 daily per bed until it reached a figure as high as $11 to $12 daily per bed in some institutions. There are few medical institutions with sufficient endowment to meet such burdens. Soon institutions began to cast about for means of supplementing the endowment. Then arose as a part of the educational scheme, but incidentally as an attempt to answer the problem of the cost of medical care for the middle class, the conception that full time teachers in the clinical department of university medical schools might earn funds for the school through the fees paid by patients, these sums to be applied to the conduct of the hospital. Thus, available information indicates one full time professor of surgery in a class A medical college who receives a salary of $18,000 a year and earns $125,000 a year for the institution that employs him.

In the meantime, it is well to recall, American communities have been supporting many forms of organized medical practice which have long been recognized by competent observers to be unsatisfactory, inadequate, uneconomic makeshifts. Lodge practice is the curse of small communities consisting largely of people of foreign parentage. Mutual benefit schemes have been sold by fly-by-night promoters to American wage earners. Organized clinics have entered into contractural arrangements with labor unions or unorganized groups of workers to provide a type of medical service that is by no means a sufficient service. Insurance companies sell health insurance policies for high premiums, which are required because an exceedingly small minority of the population purchase such policies. Moreover, all of the power rests with the company, and both patient and physician must in many instances resort to the courts to benefit by the policy. Finally, many industrial corporations, department stores, banks and similar businesses have evolved schemes of medical care for employees and also in some instances for the employee's family.

### PREVENTIVE MEDICINE

And then there are the health departments! From the beginning, medicine has been an individualistic profession. With the coming of the great plagues in the fourteenth and fifteenth centuries, man began to organize against disease. The first great public health council was held in the middle ages to take measures against the plague. With the establishment of modern knowledge of infectious diseases, it is recognized that there are some forms of prevention of disease in which the state or municipality can do more for the individual than he can do for himself. Typhoid, for instance, is largely controlled by the community as a whole. Its control depends on pure water supply, proper disposal of sewage, clean food and the isolation of the typhoid carrier. No doubt, the application of community sanitation and hygiene to the prevention of infant mortality, the elimination of smallpox, and the control of typhoid and the acute infectious diseases has been largely responsible for the increased longevity of which we proudly boast. However, it remains to be established that heart disease, diabetes, cancer and other degenerative disorders, which constitute the chief causes of death in the present decade, are to be controlled by any procedure applied to the community as a whole. The recognition, the prevention and the treatment of these disorders is distinctly a problem affecting the individual and in which only another individual can function satisfactorily as a diagnostician and therapeutist. It remains to be established that any organization or corporation can undertake periodic physical examination to better advantage than can the family physician. The disorders of middle life demand individualization above everything else. The physician who knows the patient, his family history, his business career, and the social and mental aspects of the patient's life, is best fitted to advise him concerning prophylaxis against decay.

Here, then, is the current scene—a sketchy map of the present status of medical practice. The system reveals most medical care in the hands of general practitioners and specialists working in a vast number of hospitals. By this means the majority of our people are receiving medical care that must be of considerable adequacy because certainly our morbidity and our mortality rates compare favorably with those of other civilized countries, with or without systems of compulsory health insurance or state medicine.

Nevertheless it would be folly to claim that the best type of medical care is available to all the people for a price that they can afford to pay and that seems to be the ideal that is sought. Health departments are greatly concerned with preventive medicine, and the majority of private practitioners, especially the specialists, but slightly. Hence there proceed innumerable experiments in changing the nature of medical practice and, from many social leaders, cries for a revolution.

### EVOLUTION AND REVOLUTION

It is, of course, reasonable to believe that our methods of medical practice will change to accord with changing times. We are concerned with retaining all that is good from the past and with preventing mistakes in the future. It is important that the change in medical practice come by evolution rather than by revolution. Never was there a revolution which did not swing too far and, like the pendulum, be forced to swing beyond the midline before arriving finally at the logical center.

The prophets who endeavor to predict the nature of medical practice for the future divide themselves into two groups. On one hand are those who feel that the individualistic practice of medicine, as it has existed in the past, must be supplemented by forms of organized medicine which will offer modern scientific medical care on terms that make it economically and psychologically easy of attainment. On the other hand are those who feel that, for the good of both the public and the practice of medicine, there should be no further evidence of governmental control or interference in the field of health and of medicine until sufficient study has been given to assure the retainment in medical practice, under any new plan, of those factors which have brought modern scientific medicine to its present estate.

dation of the profession of medicine. Evidence is available to indicate that several such experiments have succeeded financially only because they exploited both the patient and the physician who were concerned. It is not surprising that any self-respecting profession should refuse to become party to such plans. As essential factors in experiments in medical practice, physicians must be permitted a voice in determining the conditions of the experiment, and the final voice in determining the medical conditions.

### EXPERIMENTS ABROAD

Whatever the public wants and is willing to pay for, it gets. There does not seem as yet to have been developed in any country a complete system of medical care that can be called satisfactory. Of the countries where there is compulsory sickness insurance, free choice of physician exists only in Great Britain, France, Luxembourg, Bulgaria and Chile. In their recent report, Drs. Simons and Sinai[1] point out that the number of claims and the lengths of illness have invariably increased wherever sickness insurance has been established. Whenever payment for the cost of disease is associated with the dole or with payment for unemployment, the number of abuses multiplies alarmingly. Sickness benefit may be a poor substitute for wages, but among low paid workers, among domestics and in periods of great unemployment, it becomes at least some sort of substitute for lack of funds.

Even the Russians have not been so foolhardy as to endeavor to eliminate the personal factor in medical practice. "There have been many suggestions for the suppression of private practice," writes Grossman[2] of Smolensk, "but the National Public Health Commission has taken no direct action. The psychologic factor in sickness demands the better qualified and specialized physician and he is in private practice."

And another Russian physician, I. M. Gubinskiy,[3] writes:

> Medicine has been calling for additional trained personnel. Since state and cooperative medicine have not been able to cover the whole territory, private practice has had to do the rest. The increased demand for medical aid is due first to increase in education and, second, in spite of a decrease in mortality, to an increase in disease. Third, there has been an increase in simulated illness encouraged by socialized insurance. The increase in the number seeking medical aid has resulted in overcrowded dispensaries and long waiting lines as well as decreased medical attention for each patient examined. When on examination the patient is diagnosed for treatment, he has no other alternative than the community dis- ensary for which he obtains a written excuse from work, but no such excuse is given, the patient has to go to a private nic or to the home of a private practitioner. It is evident t improvement in state medical aid is necessary, but higher dards cannot be attained in several but possibly in ten or e years. I believe that present private practice in the form ffices or collective clinics has its *raison d'être*. The private cian does not earn more than a state physician; but the t is given, instead of seven to eight minutes, fifteen or to thirty minutes of the private physician's time. Then s the problem of the dual character of some state phy- , who are also engaged in private practice at home. But number of doctors is small, this has become a neces- To discourage private practice by state physicians, it is sted that the number of physicians should be increased, is can be accomplished by increase in state salaries and also boycotting of those engaged in private practice. At any rate it is suggested that the young group of physicians should be discouraged from private practice and in time stricter and stricter measures taken against private practice.

### THE EXPERIMENTS WITH THE CURRICULUM

There has been a constant struggle to fit the curriculum of the medical school to the changing medical needs of the nation. The suggestion has been made that two types of physicians be trained—short term doctors for country cases and long term doctors for serious illnesses. Such a panacea is so obviously ridiculous as to require but a moment's consideration. Already there are among us such short term healers of sickness as the osteopaths, the naturopaths and the chiropractors. Once in the practice of healing, they do not limit themselves to any variety of disease. Moreover, they concentrate in the cities and seek the wealthiest clientele, by no means offering for the wage earner a substitute for a physician nor for the farmer a doctor of easy access. Actually the patient remote from a hospital or the possibility of consultation demands the highest type of physician that modern medical education can develop.

The suggestion has been made that little or no attention be given to the specialties in the schools but that they confine themselves to the training of general practitioners, leaving to those who wish to specialize opportunity for graduate education in graduate schools or as assistants. The general practitioner must, however, be a specialist in every field. He never knows the moment when he may be called on to perform the most difficult of surgical operations or to diagnose the most insidious disease. Furthermore, as long as the rewards of specialization are so superior to those of general practice, the specialties are worth working for.

Few people realize that modern medical care, even at the hands of general practitioners, demands the vast armamentarium that it requires or calls into practice such a tremendous number of assistants and technicians. Labor costs are invariably the highest costs in any professional field. It has not yet been shown that it is possible to give competent medical care in the 10 per cent of difficult cases without expert laboratory, x-ray, dietetic and similar advice.

The principles that have produced some 50 per cent of specialists in a profession in which 85 per cent of the work to be done could be done by general practitioners are, no doubt, the same principles that apply in every other human occupation. The rewards of the specialist, the hours of work, the interest of his occupation are such as to make for specialization an appeal greater than that of general practice. When the rewards of the general practitioner and the interest of his work become such that general practice can compete as an attraction with the specialties, more physicians, being human beings, will become general practitioners.

### THE GENERAL PRACTITIONER AND PREVENTIVE MEDICINE

It has become apparent that the general practitioner of the future will depend largely for his existence on the practice of preventive medicine as well as on the treatment of disease. Strangely there has developed—no doubt, largely by the effects of demonstrations, the actions of public health authorities and the preachings of social workers—the idea that only curative medicine is to be paid for: that preventive medicine is the duty of the state, and that it is a function which the state

ubinskiy, I. M.: Vestnik Sovrenennoi Meditsini, 1928, number 5, small communities consisting largely of people of foreign parentage. Mutual benefit schemes have been sold by fly-by-night promoters to American wage earners. Organized clinics have entered into contractural arrangements with labor unions or unorganized groups of workers to provide a type of medical service that is by no means a sufficient service. Insurance companies sell health insurance policies for high premiums, which are required because an exceedingly small minority of the population purchase such policies. Moreover, all of the power rests with the company, and both patient and physician must in many instances resort to the courts to benefit by the policy. Finally, many industrial corporations, department stores, banks and similar businesses have evolved schemes of medical care for employees and also in some instances for the employee's family.

### PREVENTIVE MEDICINE

And then there are the health departments! From the beginning, medicine has been an individualistic profession. With the coming of the great plagues in the fourteenth and fifteenth centuries, man began to organize against disease. The first great public health council was held in the middle ages to take measures against the plague. With the establishment of modern knowledge of infectious diseases, it is recognized that there are some forms of prevention of disease in which the state or municipality can do more for the individual than he can do for himself. Typhoid, for instance, is largely controlled by the community as a whole. Its control depends on pure water supply, proper disposal of sewage, clean food and the isolation of the typhoid carrier. No doubt, the application of community sanitation and hygiene to the prevention of infant mortality, the elimination of smallpox, and the control of typhoid and the acute infectious diseases has been largely responsible for the increased longevity of which we proudly boast. However, it remains to be established that heart disease, diabetes, cancer and other degenerative disorders, which constitute the chief causes of death in the present decade, are to be controlled by any procedure applied to the community as a whole. The recognition, the prevention and the treatment of these disorders is distinctly a problem affecting the individual and in which only another individual can function satisfactorily as a diagnostician and therapeutist. It remains to be established that any organization or corporation can undertake periodic physical examination to better advantage than can the family physician. The disorders of middle life demand individualization above everything else. The physician who knows the patient, his family history, his business career, and the social and mental aspects of the patient's life, is best fitted to advise him concerning prophylaxis against decay.

Here, then, is the current scene—a sketchy map of the present status of medical practice. The system reveals most medical care in the hands of general practitioners and specialists working in a vast number of hospitals. By this means the majority of our people are receiving medical care that must be of considerable adequacy because certainly our morbidity and our mortality rates compare favorably with those of other civilized countries, with or without systems of compulsory health insurance or state medicine.

Nevertheless it would be folly to claim that the best type of medical care is available to all the people for a price that they can afford to pay and that seems to be the ideal that is sought. Health departments are greatly concerned with preventive medicine, and the majority of private practitioners, especially the specialists, but slightly. Hence there proceed innumerable experiments in changing the nature of medical practice and, from many social leaders, cries for a revolution.

### EVOLUTION AND REVOLUTION

It is, of course, reasonable to believe that our methods of medical practice will change to accord with changing times. We are concerned with retaining all that is good from the past and with preventing mistakes in the future. It is important that the change in medical practice come by evolution rather than by revolution. Never was there a revolution which did not swing too far and, like the pendulum, be forced to swing beyond the midline before arriving finally at the logical center.

The prophets who endeavor to predict the nature of medical practice for the future divide themselves into two groups. On one hand are those who feel that the individualistic practice of medicine, as it has existed in the past, must be supplemented by forms of organized medicine which will offer modern scientific medical care on terms that make it economically and psychologically easy of attainment. On the other hand are those who feel that, for the good of both the public and the practice of medicine, there should be no further evidence of governmental control or interference in the field of health and of medicine until sufficient study has been given to assure the retainment in medical practice, under any new plan, of those factors which have brought modern scientific medicine to its present estate.

### CONTROLLED EXPERIMENTS

It has been well emphasized that the medical profession has led in the field of research in science but that it is among the most conservative of groups when considering possible experimentation in the fields of social organization. Scientific physicians demand laboratory study for confirmation of the value of any remedy before applying that remedy to their patients. They demand suitable controls before they are willing to accept evidence. They feel, no doubt, that the criteria which apply to the judgment of a scientific experiment should be used in evaluating experiments in social fields. They are unwilling to accept the word of the promoter of a demonstration that the demonstration has been an unqualified success. They are inclined to wait until the subjects of the demonstration, namely, the physician and the people of the community, submit their evidence in the matter. They are unwilling to accept the unsupported statement of the economist that the best medical care must be given to all the people at a price that they can afford to pay, until the economist can show that such care can be provided at a price that people can afford to pay, and until the economist can work out systems for controlling the supplies of food, fuel, clothing and suitable homes for these same people. Already it has been established that disease is not always caused by germs—that sometimes housing and food play vital parts in its prevention.

The medical profession has been averse to experiments which do not seem to have been properly organized or directed, and which do not take into account correctly the medical factors that are significant. Far too often, experiments in changing the nature of medical practice have been conceived, outlined and put into effect by lay directors without suitable medical advice. Such experiments not infrequently lead to the degradation of the profession of medicine. Evidence is available to indicate that several such experiments have succeeded financially only because they exploited both the patient and the physician who were concerned. It is not surprising that any self-respecting profession should refuse to become party to such plans. As essential factors in experiments in medical practice, physicians must be permitted a voice in determining the conditions of the experiment, and the final voice in determining the medical conditions.

### EXPERIMENTS ABROAD

Whatever the public wants and is willing to pay for, it gets. There does not seem as yet to have been developed in any country a complete system of medical care that can be called satisfactory. Of the countries where there is compulsory sickness insurance, free choice of physician exists only in Great Britain, France, Luxembourg, Bulgaria and Chile. In their recent report, Drs. Simons and Sinai [1] point out that the number of claims and the lengths of illness have invariably increased wherever sickness insurance has been established. Whenever payment for the cost of disease is associated with the dole or with payment for unemployment, the number of abuses multiplies alarmingly. Sickness benefit may be a poor substitute for wages, but among low paid workers, among domestics and in periods of great unemployment, it becomes at least some sort of substitute for lack of funds.

Even the Russians have not been so foolhardy as to endeavor to eliminate the personal factor in medical practice. "There have been many suggestions for the suppression of private practice," writes Grossman [2] of Smolensk, "but the National Public Health Commission has taken no direct action. The psychologic factor in sickness demands the better qualified and specialized physician and he is in private practice."

And another Russian physician, I. M. Gubinskiy,[3] writes:

> Medicine has been calling for additional trained personnel. Since state and cooperative medicine have not been able to cover the whole territory, private practice has had to do the rest. The increased demand for medical aid is due first to increase in education and, second, in spite of a decrease in mortality, to an increase in disease. Third, there has been an increase in simulated illness encouraged by socialized insurance. The increase in the number seeking medical aid has resulted in overcrowded dispensaries and long waiting lines as well as decreased medical attention for each patient examined. When on examination the patient is diagnosed for treatment, he has no other alternative than the community dispensary for which he obtains a written excuse from work, but if no such excuse is given, the patient has to go to a private clinic or to the home of a private practitioner. It is evident that improvement in state medical aid is necessary, but higher standards cannot be attained in several but possibly in ten or more years. I believe that present private practice in the form of offices or collective clinics has its *raison d'être*. The private physician does not earn more than a state physician; but the patient is given, instead of seven to eight minutes, fifteen or twenty to thirty minutes of the private physician's time. Then there is the problem of the dual character of some state physicians, who are also engaged in private practice at home. But since the number of doctors is small, this has become a necessity. To discourage private practice by state physicians, it is suggested that the number of physicians should be increased, and this can be accomplished by increase in state salaries and also boycotting of those engaged in private practice. At any rate it is suggested that the young group of physicians should be discouraged from private practice and in time stricter and stricter measures taken against private practice.

### THE EXPERIMENTS WITH THE CURRICULUM

There has been a constant struggle to fit the curriculum of the medical school to the changing medical needs of the nation. The suggestion has been made that two types of physicians be trained—short term doctors for country cases and long term doctors for serious illnesses. Such a panacea is so obviously ridiculous as to require but a moment's consideration. Already there are among us such short term healers of sickness as the osteopaths, the naturopaths and the chiropractors. Once in the practice of healing, they do not limit themselves to any variety of disease. Moreover, they concentrate in the cities and seek the wealthiest clientele, by no means offering for the wage earner a substitute for a physician nor for the farmer a doctor of easy access. Actually the patient remote from a hospital or the possibility of consultation demands the highest type of physician that modern medical education can develop.

The suggestion has been made that little or no attention be given to the specialties in the schools but that they confine themselves to the training of general practitioners, leaving to those who wish to specialize opportunity for graduate education in graduate schools or as assistants. The general practitioner must, however, be a specialist in every field. He never knows the moment when he may be called on to perform the most difficult of surgical operations or to diagnose the most insidious disease. Furthermore, as long as the rewards of specialization are so superior to those of general practice, the specialties are worth working for.

Few people realize that modern medical care, even at the hands of general practitioners, demands the vast armamentarium that it requires or calls into practice such a tremendous number of assistants and technicians. Labor costs are invariably the highest costs in any professional field. It has not yet been shown that it is possible to give competent medical care in the 10 per cent of difficult cases without expert laboratory, x-ray, dietetic and similar advice.

The principles that have produced some 50 per cent of specialists in a profession in which 85 per cent of the work to be done could be done by general practitioners are, no doubt, the same principles that apply in every other human occupation. The rewards of the specialist, the hours of work, the interest of his occupation are such as to make for specialization an appeal greater than that of general practice. When the rewards of the general practitioner and the interest of his work become such that general practice can compete as an attraction with the specialties, more physicians, being human beings, will become general practitioners.

### THE GENERAL PRACTITIONER AND PREVENTIVE MEDICINE

It has become apparent that the general practitioner of the future will depend largely for his existence on the practice of preventive medicine as well as on the treatment of disease. Strangely there has developed—no doubt, largely by the effects of demonstrations, the actions of public health authorities and the preachings of social workers—the idea that only curative medicine is to be paid for: that preventive medicine is the duty of the state, and that it is a function which the state will assume. There are two types of preventive medicine: first, that for which the community is primarily responsible and which only the community can perform; second, that which involves action of one individual on another and which should always be a function of private practice. Significant in this connection is an incident reported as a part of a recent demonstration for the control of diphtheria. An enlightened health officer persuaded his community by the use of posters in street cars and on busses, by lectures over the radio, by announcements in the newspapers, and even by circulars sent directly to homes that the administration of toxin-antitoxin or of toxoid to children is a most important step in the control of diphtheria. This health officer realized, of course, the danger of interfering with the confidence of patients in their family physicians, so his suggestion concluded: "Ask your physician, or come to the health department."

[2] Grossman, P.: Sovetskiy Vrach, 1930, number 1, p. 10.

[3] Gubinskiy, I. M.: Vestnik Sovremennoi Meditsini, 1928, number 5, p. 302.

Following is a typical conversation that ensued between a mother and the family doctor:

"Doctor, do you believe in giving of toxoid to prevent diphtheria?"

"Yes, indeed."

"Do you use the same serum that the health department uses?"

"Yes, indeed."

"What do you charge, doctor?"

"Five dollars."

"Doctor, does the health department give the same treatment that you give?"

"Yes."

"Do they charge anything?"

"No. They take the funds out of the taxes."

"Well, doctor, wouldn't I be a simpleton to pay you $5 when I can get the same service from the health department for nothing?"

And being an honest doctor, he encouraged her to get the service from the health department because he recognized the importance of the preventive procedure. The physician in private practice cannot compete in the field of preventive medicine with state-owned and tax-paid-for services of this character.

### THE PHYSICIAN IN INDUSTRY

If every steel mill, department store and similar industry employs salaried physicians to provide medical service to employees, three fourths of the people in this country who earn money will be removed as a possible source of income from private practitioners. Then, by the laws of nature, practitioners will no doubt disappear.

There would seem to be no reason why any great industry that wishes to safeguard the health of its employees should not provide physicians to be consulted by these employees in emergencies, to advise them regarding the prevention of disease, and, *if necessary*, even to give them medical care. But industrial physicians should not compete unfairly with other physicians in the community; they should not employ methods for the promotion of their practices beyond the methods available to other physicians. They should not, for a bare living salary, endeavor to treat employees and their families, because they cannot do justice to their patients and thereby they degrade the profession that they serve.

### UNIVERSITY PRACTICE

It is reasonable to believe that universities and medical schools will continue to conduct hospitals in which patients will be treated for pay. It is not conceivable that such institutions will be able to finance their hospitals without fees from patients. In conducting hospitals, however, universities should limit, as far as possible, competition on an unfair basis with the men that it educates and places in the community. These graduates have a right to fairness. The size and expansion of a university clinic should be limited to the number of beds necessary for teaching purposes. The fees established by the university, when it takes care of the wealthy, should not be markedly less than the usual fees in the community. It seems doubtful, although I believe Mr. Michael Davis has expressed the hope, that great expansion of university clinics will in any measure answer the cry for suitable care of the great middle class and the wage earner. The function of the university and the medical school should be teaching and research, not the practice of medicine.

### THE TREND OF PRIVATE PRACTICE

Our present social organization is complicated. It varies greatly from city to city, from village to village, from state to state; it varies tremendously from person to person, from industry to industry. It is inconceivable that any single plan will be developed for a system of medical practice applicable to every inhabitant of our country. The problem of providing funds for medical care is, after all, not a medical problem; it is a problem for bankers, economists and statesmen. Insurance is a means of saving for an emergency, for the replacement of lost property and lives. Insurance may be compulsory or voluntary. The American people should never consent to compulsory health insurance —but in some of our states they may. Then the remaining states will be able to watch the experiment. True, there are available excellent reports of the experiments abroad. The books by Simons and Sinai, and by Newsholme,[4] and the report of Rappleye for the Commission on Medical Education have shown that thus far not one system has attained complete satisfaction. Conceivably a system might be devised that will provide free choice of physician, insure adequate practice of preventive medicine, place responsibility on the patient for maintaining the insurance and on the physician to the patient, stimulate initiative and research among physicians who participate, and be free from political manipulation, graft and other weaknesses usually associated with state control. But, alas, such a system has not appeared abroad, and the history of American statesmanship and government control in other fields does not indicate its likelihood among us.

### HEALTH EDUCATION

There remains the necessity of teaching the people the importance of saving for sickness as they now save in anticipation of postponed pleasure or death. Great insurance companies spend immense sums on education of their policyholders with a view to causing those policyholders to live longer and thereby to postpone the date of final payment on their life insurance. With the establishment of health insurance abroad, the amount of money spent on medical care increased from three to five times. The reports of the Committee on the Costs of Medical Care indicate that we shall have to spend much larger sums than are now spent to give to all our people the best type of medical care. It has been shown that advance in medical science has made modern diagnosis and treatment in the

---

[4] Newsholme, Sir Arthur: International Studies on the Relation Between the Private and the Official Practice of Medicine, Baltimore, Williams and Wilkins Company, 1931.

10 per cent of serious disease exceedingly costly. We have the physicians and the equipment to provide the best, but apparently the people do not have or will not save the money to pay for it.

An extensive campaign of education in newspapers, in magazines, directly by mail, through lectures and over the radio in behalf of voluntary sickness insurance might result in causing a sufficient number of people to apply for such insurance if it can be offered at a price that could be met by the wage earner. Simons and Sinai consider any voluntary system merely a short bridge to a compulsory plan.

People know that death is inevitable. In teaching preventive medicine, we have emphasized that sickness may be prevented. Today we know that some sickness for every family is just as inevitable as death, and unless obstetrics continue to be inevitable there will be no population for the future. Let us, therefore, teach the worker that 2,000,000 people are sick every day in 120,000,000 population, and that this number is not likely to change greatly in the future, even with considerable advance in the application of preventive medicine. Even should disease itself be largely outlawed from the human race, degeneracy and decay and ultimately death must be the lot of all of us. Associated with death and decay come inevitable illnesses that must be provided for; the need for the physician and for curative medicine will never disappear.

### SUMMARY

To recapitulate, great progress in medical science has substituted for the family physician a complex system including hospitals, laboratories, technicians, dieticians, nurses, and a greatly increased equipment and personnel.

The family physician will always be the most economic and practically the most satisfactory physician for 90 per cent of human ailments.

The remaining 10 per cent of human ailments require hospitalization and specialization.

Modification of the curriculum or abbreviation will not lead to a greater number of general practitioners. The rewards of general practice must be made attractive in comparison with the rewards of specialization.

The general practitioner must become increasingly a practitioner of preventive medicine, and people must learn that preventive medicine is, like curative medicince, to be paid for, particularly because it is always worth more than it costs.

Organized medical practice in the form of groups, university clinics, industrial medicine, insurance practice and contract practice may have definite fields in medical practice. For the good of the public and for the advancement of medical science, they should limit themselves to the fields for which they are fitted.

People must learn to save for sickness as they now save for luxuries or in anticipation of death.

If the people cannot be educated to saving for sickness, voluntary health insurance or even compulsory health insurance will probably come.

The physician in private practice will not disappear. Under every compulsory health insurance system, and even in Soviet Russia, he persists because only a personal physician can function efficiently in a vast number of types and cases of disease.

Until human bodies and minds are standardized—an antibiologic conception—individual mutual responsibilities between patient and physician must be maintained.

535 North Dearborn Street.

# ORGANIZED MEDICINE AND PUBLIC HEALTH

J. N. BAKER, M.D.
Health Officer of the State of Alabama
MONTGOMERY, ALA.

Neither an attitude of smug complacency nor a smoke-screen of tradition affords a proper method of approach for the solution of the many knotty problems now facing organized medicine. The solvent searchlight of science, playing for the past two or more generations on many of Nature's hidden secrets, has served to dissipate the veil of mystery in which many professional theories and traditional practices have formerly been wrapped. Speculative hypotheses no longer appease the modern materialistic mind which now clamors loudly for a type of medical service that will protect its physical body from the ravages of disease proved through scientific discovery to be preventable. So precipitous, so speedy has been this shift, and so insistent have been the demands made that, with reason enough, the medical profession, with tap-roots dipping deep down into the centuries, has had difficulty in adjusting itself to this changing order.

Life as it is lived today is not, from a sociologic standpoint, the simple, ameba-like thing it was a few generations ago, and all factors contributing to its make-up—not the least of which is medicine—must so adjust their activities as to conform to this changed life. Herein lies the medical profession's problem today; 'tis one largely of adjustment, or better, possibly, of readjustment. Granted this premise, let us proceed, in a brief fashion, to draw therefrom certain logical conclusions:

Any readjustment in medicine, to be successful, must spring spontaneously from within rather than be forced from without. Not merely the preservation and development of the profession of medicine depend on the success of this readjustment but, to a greater extent than one is wont to realize, the preservation and development of the human race depend on it.

It is precisely because medicine is the father of philanthropy and the sine qua non of social uplift that every new experiment in government, social economy or social betterment, seeks to absorb medicine and to make of it a tool in the prosecution of its enterprises. Organized medicine has met disease in open combat and won decisive victories over it; now it must develop and control statesmanship, as well as its cunning cousin, political intrigue, in order to meet these human forces on equal terms.

Public health has, within the last twenty-five years, come to a place of usefulness in furnishing much of the machinery by which organized medicine is enabled to cope with disease. Demonstration clinics, the function of which, in a last analysis, is educative, have served to create a new interest in medical supervision and thereby to bring many patients to the offices of physicians for continued treatment. The free laboratory services, now in operation in most states for the use of physicians, make diagnosis easier and more exact and thereby materially increase the confidence of the patient in the physician. The powers inherent in this new piece of machinery are likewise the object of covetous regard by sociologic and industrial enterprises. It is

---

Read before the joint meeting of the Section on Practice of Medicine and the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

conceivable that public health agencies, were it not for their firm and scientific moorings to organized medicine, might be absorbed in an effort to utilize them in a struggle to control medicine.

Public health forces, particularly the health officer, are by the very nature of their activities brought into intimate and constant contact with forces that are competing for power and managerial control over certain types of medical service. For example, workmen's compensation boards, the sociologic aspects of venereal disease problems and the economic factors of tuberculosis control, all inevitably lead to such contacts. Inherent in these and other like instances are to be found the vested interests of a corporation, an industrial enterprise, or a merger which combines the interests of several such members. These vested interests frequently, and perhaps usually, are subversive of free and untrammeled exercise of the prerogatives of a personal physician. His age-old motto, "consideration of the patient's welfare first," gives way to one well understood but seldom expressed: "insofar as the patient's welfare coincides with advantage to the corporation, let it come first." The physician's efforts to render expert medical service, under these circumstances, are likely to be cast in a mold, fashioned by an efficiency engineer whose real objective is mass production of merchandise which can be sold at profit. Such a system places a higher premium on returning a laborer to his job than on returning a contented individual to the community or a healthier and happier parent to his family.

Some of the voluntary health agencies, though ostensibly free from the taint of vested interest, exhibit an arrogant assumption that "we know best what is good for the public weal." Every artifice of publicity and propaganda is utilized to influence the lay mind in ways that tend to uphold interests of the voluntary agency and to overthrow the dignity and usefulness of the medical profession. Physicians must meet the conditions created by this complex alinement of artifice against artistry and science. These conditions cannot be met, nor the problems solved, either by an attitude of resentment or by one of indifference. Neither can a solution be reached by a campaign of vituperation. Only a constructive policy of leadership within the ranks of organized medicine can bring order out of chaos and fulfil the prophecy of Descartes: "If ever the human race is raised to its highest practicable level intellectually, morally and physically, the science of medicine will perform that service." René Descartes died in 1650, but his challenge to scientific medicine comes down through the ages, reverberating from peak to peak of victorious achievement.

But not all of the achievements of organized medicine, even the victorious ones, which we traditionally glorify, have been without their undesirable cumulative effects. The average modern doctor still hugs to his bosom the thought of a long list of dependent families for whom he cares as a matter of course, almost as if they were members of his own family. Might he not do well to contemplate such gratuitous service in the light of distorted modern psychology, which asks, "How can we get something for nothing?" Does not a logical question immediately present: "How far can organized medicine, together with the rest of society, be held responsible for fostering such an attitude?" Apparently, it is but a short step in the thinking of otherwise self-respecting persons to "Why pay personally for medical and hospital service when others can be found to do this for us?" The village doctor, so beautifully portrayed by Balzac, in the traditional rôle of "Good Samaritan," was a character in keeping with the social order of a century ago. But, who will question that the present maelstrom of contending social forces are bent on bettering the human race through medical and public health services, without considering very seriously what the leaders of these services think as to how these ends may and may not be advantageously sought? More than anything else, at this time, an authoritative voice is needed.

Unquestionably such a voice should emanate from organized medicine, while public health forces should operate as a broadcasting service, corroborating, interpreting and demonstrating the feasibility of a plan of administration that recognizes the fundamental soundness of conserving the welfare of scientific medicine, as secondary only to the welfare of the human race. Indeed, the intrinsic worth of the former may be said to be inherent in the latter.

Without effort either to define or discuss the forbidding vagaries of "state medicine," one must realize that no sane approach can be made to the problem that ignores the important fact that in any moot, sociologic and economic question, be the decision right or wrong, the voice of the people will ultimately prevail.

If this is granted, what are the possibilities now confronting organized medicine?

As a first possibility, various types of medical service may be designed according to the intellectual lights or pecuniary interests of nonmedical groups to meet the needs of complex, modern [illegible] will unquestionably operate without a due regard to the views, interests and leadership of organized medicine. It is probable, also, that they will be administered without a due regard to rights of private citizens to select their own physicians.

The fact that organized medicine may not be accorded the privilege of deciding for itself what are the highest types of service it can render to society will constitute an additional defect in such a plan of operation. With the voice of scientific medicine thus silenced or ignored, how can the avenues for the bestowal of medicine's highest gifts be kept open?

In contrast to the manifest disasters foreshadowed in the foregoing paragraphs, a readjustment both acceptable and workable to all concerned might be had through a firm fusion of all of the powers of leadership now to be found in the professions of medicine and of public health. Such a readjustment, it is believed, might be perfected with every due regard both to the general public and to the professional ideals and interests of organized medicine.

Public health activities are sometimes mistakenly conceived to be inconsistent with the best interests of organized medicine. A careful examination of the facts with relation to existing instances will reveal that the highest type of state-supported preventive medicine may be conducted with full and complete regard for the prerogatives of private physicians, as well as for the rights of the general public. So conducted, these activities unquestionably tend to place patients in the hands of practitioners of medicine. When evidence of incompatibility arises, it can usually be traced either to a misunderstanding on the part of the physician or to misdirected zeal on the part of the health worker. In either case, a frank discussion of the matter can be depended on to clear up the misunderstanding or to correct the misdirected effort. As the teachings of health authorities with regard to disease prevention begin to seep into the mass mind, the field of medicine will be extended and its precision and scope will be vastly increased. Good medical practice will mean the unhampered pursuit of scientific medicine and its establishment as the basic essential of a sound program of public health. These two phases of modern medical achievement are rightfully corollaries, not competitors. Furthermore, it would be nothing less than pitiable ever to see these two mutually indispensable phases of modern medicine arrayed against one another. How can either overlook the fact that, without the other, it would be working with little thought and less vision in a blind alley?

Organized medicine and public health hold, within their united grasp, every essential for the successful readjustment of the services of healing and prevention to meet the needs of the world today. These essentials include devotion to scientific achievement, inextinguishable ardor for the public weal, sagacity in organization and administration of plans. When such plans have been jointly evolved, approved and accepted by a majority of the membership of both groups, then the profession shall be in position to dictate terms to every agency seeking to finance medical service. Until our house is set in order and unless it is done successfully, organized medicine will be subjected, more and more, to dictation from outside its own ranks, and public health administration will find itself repeatedly circling in its own tracks and in utter futility.

That the profession of medicine will suffer in consequence is of relatively minor importance. This lesser calamity will be swallowed up in the greater disaster of the human race which will not be raised to its highest practicable level intellectually, morally and physically, because scientific medicine will have failed to point the way by which this service might be had. This will prove to be, not merely the humiliation of medicine; it will be the tragedy of mankind.

## ABSTRACT OF DISCUSSION

### ON PAPERS OF DRS. LEE, FISHBEIN AND BAKER

**Dr. Stewart R. Roberts**, Atlanta, Ga.: When one hears so timely a paper as that by Dr. Lee, one can hardly help thinking of a country physician and general practitioner, Edward Jenner, who discovered the first universal application of preventive medicine in his vaccination against smallpox. If Jenner could do that so long ago, how much can we clinicians do in preventive medicine? Emphasis on preventive medicine is a state of mind, of preventive intent and interest, always watching and looking for the personal contact and the personal teaching that would prevent illness. I am disposed to think that in our personal relations with our patients, so far as the preventive phase of it goes, we use the subjunctive too frequently. We need to use the indicative mode in our personal relations regarding preventive medicine with our patients. Sometimes we need to use the imperative. Health is much more than just feeling well. For thousands of years we have had the incubus that the physician is but a curative agent. Ask the little boy who the doctor is and he will tell you he is the man who goes around making sick people well. We now have the newer view. Many diseases will disappear, and more and more of us, as the younger graduates come on, will lay more sensible and more productive emphasis on balanced living.

**Dr. H. F. Vaughan**, Detroit: There is one aspect of the problem of medical cooperation with public health agencies which has not been emphasized and that is that at present there is an outstanding need for cooperation of this character. I know of no more opportune time than the present depression for efficient cooperation between the medical profession and the public health agencies. Health departments are suffering in their appropriations. They are being cut. There is greater need than ever before for the efficient expenditure of public funds and for the getting together of the most efficient type of machinery concerning public health. I think we can all agree that public health cannot be divorced from curative medicine; that the two go hand in hand. The Committee on the Costs of Medical Care has shown us that there are sick at a given time about 2 per cent of our population; 98 per cent are well or supposedly well. From my point of view, there is far more satisfaction to the medical profession and greater remuneration to the medical profession in taking care of the 98 per cent who are well than trying to collect bills from the 2 per cent who happen to be ill. It seems to me that the answer to the bugaboo of state medicine, so far as preventive medicine is concerned, lies entirely in a program of medical participation. The medical societies throughout the land should take the initiative in recapturing, as it were, for the medical profession the program of public health work. We come together occasionally and listen to discourses as to the difficulties inherent to a program of this sort, and I can't help becoming more or less agitated because we don't seem to get anywhere. Year after year we talk about the same thing. In one large city of a million and a half population such a program has actually been put in operation through the initiative of the county medical society. The health department and the medical society jointly have participated in a program of preventive medicine. We started in with a program of diphtheria protection. Three years ago we did away with all free clinics for the immunization of persons against diphtheria. We have not had a free clinic in three years, and this city has the highest percentage of protection between 1 year and 10 years of age when children have diphtheria, of any large community in the United States. Seventy-five per cent of the children of preschool age, 80 per cent of the school children, and 50 per cent of the youngsters under 1 year of age are protected against diphtheria. In the year 1931 this meant $200,000 in the pockets of the physicians who participated in this cooperative enterprise. All the service was rendered in the physician's office, with no free clinic by the health department. During the same period of time, without any special pressure or undue exertion, vaccinations against smallpox among the preschool group increased from 22 to 45 per cent, and the physicians were paid for this service. To my mind, the answer is the continued maintenance of public health machinery in our country of an adequate but limited character, and real participation on the part of organized medicine.

**Dr. E. Starr Judd**, Rochester, Minn.: The family physician is the most economical and the most satisfactory physician. I agree with Dr. Fishbein that rewards of the general practitioner must be made comparable to those of the specialist. The general practitioner can make thorough examination without elaborate equipment. He can keep abreast of the times by reading well recognized medical journals and by attending clinics and medical meetings. Preventive medicine is becoming a very definite part of the work of the general practitioner, and he should be paid for his services in this direction. He can carry out this work in a more satisfactory manner than any one else because he has intimate knowledge of his immediate district. This opens a new field of activity, income and real service. Some feel that group practice can be carried on without regard to the personal element. From experience of many years, I know that success in this form of practice is impossible without regard to this personal relationship. University clinics, industrial medicine, insurance practice and contract practice quite likely have a limited place in our work. It is difficult for me to see how the personal relationship between physician and patient can be maintained in these forms of practice, how the best results for the patient can be obtained, and, finally, how these forms of practice can help advancement of medical science. A recent survey shows the following: Men are entering the practice of medicine at a somewhat later age than previously. Although 47.7 per cent of the population of the United States is in communities of less than 5,000, only 19 per cent of the graduates of the year 1925 were practicing in communities of that size. Of the graduates of 1920 and 1925, 17.6 per cent were occupying full time salaried positions six years after graduation. Approximately 35 per cent of the graduates of 1920, and also of 1925, have limited their practice to a specialty within six years after graduation. More than 70 per cent look forward to limiting their practice ultimately to a specialty. A little more than half of those who limit their practice to a special field do so without having had any experience in general practice. The number of men specializing in eye, ear, nose and throat and pediatrics is decreasing. Specialization has been overdone a little, and many are setting themselves up as specialists who are not thoroughly qualified. The American Medical Association, cooperating with other associations interested in this problem, should endeavor to indicate who is entitled to designate himself as a specialist.

Dr. G. Henry Mundt, Chicago: The contacts which both men in government service and men in private practice must make are with the general public and with the profession. This contact with the general public has been carried out over the country, I think, much more satisfactorily by the men and women interested primarily in preventive medicine than those who are interested in the private practice of medicine. This, however, should not obtain, and with proper effort on the part of medical organizations they can make contacts which will be very satisfactory because in the final analysis the only way problems of medicine can be solved is by education of the general public. I think Dr. Fishbein is right. The average medical man is overtrained with mechanism but not overtrained with ability to think. One of the difficulties with this problem which is facing medicine is that the average man in medicine has a mechanistic view of medicine. He is entirely disposed to depend on roentgen or laboratory observations rather than on physical examination. We must get clearly in mind the extent to which universities and institutions of that kind practice medicine in competition with the private practitioner. I am convinced that the limit of material which should be used is that which is needed for teaching research. Anything beyond that is unfair to the public and to the medical profession. Unless we change our mental attitude and the mental attitude of the public concerning the practice of medicine by subsidized groups, we shall leave the 47 per cent of the general public who reside in communities of less than 5,000 very inadequately taken care of medically.

Dr. J. Cyril Eby, Plaquemine, La.: Organized medicine should cooperate with the public health workers. There is a definite field for both. When physicians as a whole concur in the fundamentals of public health principles, many of the alleged differences of opinion will automatically disappear, because it is frequently observed by health administrators that the bone of contention is not differences concerning the need for disease control measures but concerning the method of attacking the problems. I believe each community should meet its own needs as far as possible, and it is the duty of health officials, with the aid of the physicians, to educate people to the need of sanitation, hygiene and corrective procedures. Curative biologicals and medicines, if furnished the physicians, should be paid for by the individuals receiving the benefit. The health department and the physicians, working in cooperation, will eliminate useless friction and transform this wasted energy into beneficial service to the public. Every health officer here is striving to do the proper educational work so that the coming generation will look on the health department as a necessity. The older generation does not yet have this point of view, but coming generations will look on it as one of the essentials of the government and will demand adequate appropriations for the support of public health work.

---

**Absence of the Stomach.**—Those who cling to the old theory of intestinal infection in pernicious anemia may think that the deciding factor is the intestinal flora, but when we consider the frequency of megalocytic anemia in fatty diarrhea and after intestinal resection, we shall probably conclude that it is a matter of the efficiency of digestion and assimilation in the intestine. While the results of gastrectomy show that a healthy intestine can compensate for the failure or absence of the stomach, there is evidence on the other hand that disorders of the intestine may nullify the effects of perfect digestion in the stomach. We seem driven to the view that in pernicious anemia either gastric or intestinal digestion, or both, may be at fault.—Witts, L. J.: *Lancet*, March 12, 1932, page 549.

# COLLAPSE THERAPY OF PULMONARY TUBERCULOSIS IN THE NEW ENGLAND STATES

JOHN B. HAWES II, M.D.
AND
MOSES J. STONE, M.D.
BOSTON

The treatment of pulmonary tuberculosis by collapse of the affected lung as exemplified by pneumothorax, phrenicectomy and thoracoplasty represents one of the most effective means of treating this disease. A procedure by which the diseased lung is put at rest not only prolongs life, reduces the mortality from this disease and shortens what would otherwise be a long period of invalidism but, of still greater importance, hastens the patient's return to industry. Yet, certainly in New England and all over the eastern part of this country except in the great tuberculosis centers, such as Saranac Lake and Liberty, N. Y., and Asheville, N. C., the medical profession seems to hold aloof from these procedures and to look on them rather as measures of last resort. Compare pneumothorax in tuberculosis, for instance, as the most common and certainly the simplest means of putting the lung at rest, with insulin in diabetes and with liver and liver extracts in the primary anemias. Physicians are perfectly well aware of the great good that the latter two can accomplish. Yet, for the obvious reason that for every case of diabetes or primary anemia there are hundreds of cases of pulmonary tuberculosis, the total of good that can be done by the former fades into insignificance when compared with what can and should be done by collapse therapy in tuberculosis when in suitable hands and in properly selected cases. We do not mean to imply that the medical profession is ignorant of the various methods of putting the lung at rest. It is probably because the average physician has no experience in such procedures and is not equipped to carry out these methods of treatment that he is loath to recommend them to his patients. The reaction of many physicians, when the consultant suggests that pneumothorax is indicated, is too apt to be, "Oh, no, Doctor, she hasn't reached that stage yet." In our own practice this has been only too frequent an occurrence. Thus the patient and the family are persuaded against it and much precious time is lost while the disease attacks the other lung, after which all possibility of putting one lung at rest is gone forever.

The same point of view is apt to be found in many tuberculosis hospitals and sanatoriums. Often it is for reasons of economy, usually because there is no proper x-ray equipment, that pneumothorax is not done. Still more often it is because the medical personnel has had no experience along this line that many hospitals and sanatoriums for tuberculosis are not using this most effective means of helping their patients.

The public, wonderfully educated concerning tuberculosis and its treatment, in other ways, thanks to the educational campaign of the last twenty-five years, seems to be ignorant of "collapse therapy." Popular magazines are full of articles on the marvels accomplished by insulin and liver, but they contain little if anything about a far more important means of alleviating suffering and curing an infinitely more widespread and devastating disease than either diabetes or the anemias.

One of us (J. B. H.) recently asked three questions of fifty consecutive presumably intelligent lay men and women:

1. What does the word "insulin" mean to you?
2. What does "liver," not as a food but as a medicine, convey to your mind?
3. Do the words and phrases "pneumothorax," "collapse therapy," "compressing the lung," "gas treatment," "the rib operation" mean anything to you?

Each of the fifty gave satisfactory answers to the first two questions but admitted complete ignorance of the last.

We have simply selected the six New England states for this study because we live and carry on our work in one of them and are therefore much more familiar with the tuberculosis problem in New England than elsewhere. It was because we felt that this state of affairs in New England was a most unsatisfactory one, resulting in many unnecessary deaths and much equally needless invalidism and suffering, that we have undertaken this investigation. It is doubtless true that the same neglect of collapse and compression therapy in tuberculosis exists elsewhere in this country, but we felt that perhaps somewhat hyperconservative New England might be particularly derelict in this regard.

It is not easy to obtain accurate information concerning such a subject as this. The only figures at our disposal that can be said to be at all definite and certain are the yearly number of deaths from tuberculosis in each state. The remaining statistics on which such a study must be based are only approximate. Admitting this at the outset, we have therefore endeavored to obtain as accurate information as possible from every available source concerning:

Table 1.—*Deaths from Pulmonary Tuberculosis in the New England States in 1930*

| | |
|---|---|
| Connecticut | 825 |
| Maine | 371 |
| Massachusetts | 2,423 |
| New Hampshire | 206 |
| Rhode Island | 389 |
| Vermont | 208 |
| Total | 4,422 |

1. The total number of recorded deaths from pulmonary tuberculosis in each of the New England states for the year 1930.
2. The approximate number of active cases of this disease in each state for the same period.
3. The approximate number of patients with pulmonary tuberculous disease in whom some form of collapse therapy was used and, from this, the percentage of such cases with reference to the total number of patients with active tuberculosis in each state.
4. Finally, some idea, based on information from the most authoritative sources in this country, as to what might be considered a fair average percentage of the total number of active cases of tuberculosis in each community which are suitable for some form of collapse therapy and which should be given the opportunity of such treatment.

The accompanying tables show the results of our inquiry.

The figures in table 1, obtained from the respective health departments of each state, are presumably accurate although doubtless well inside the actual number of deaths from this disease. The respective mortality rates do not enter into this discussion.

In table 2 the figures as to the number of active cases of tuberculous disease were obtained by multiplying the number of deaths by 5. This factor, based on the results of the Framingham Demonstration and many other similar studies, has been approved and accepted by the National Tuberculosis Association and by the American Public Health Association as a fair means of estimating the number of active cases and is generally considered standard practice. It represents a figure probably far within the total number of cases of active tuberculous disease.

Table 2.—*Number of Active Cases of Pulmonary Tuberculosis in Each of the New England States in 1930*

| | |
|---|---|
| Connecticut | 4,125 |
| Maine | 1,855 |
| Massachusetts | 12,115 |
| New Hampshire | 1,030 |
| Rhode Island | 1,945 |
| Vermont | 1,040 |
| Total | 22,110 |

Accurate information concerning the use of pneumothorax, phrenicectomy and thoracoplasty is difficult to obtain. We have no doubt that we have missed some cases but in all probability not enough to affect the results materially. We have written personal letters to every hospital and sanatorium, public and private, in New England asking for the figures in each case. In this list we have included the larger general hospitals in which we felt that pneumothorax or some similar procedure might have been carried on. In addition, we have communicated with every specialist in diseases of the lung and in tuberculosis and with every thoracic surgeon in New England known to us. The result needs no comment. Of probably far more than 22,110 active cases of pulmonary tuberculosis in New England in the year 1930, only 928 were selected for some form of collapse treatment.

We were convinced that this proportion, 4.2 per cent, was pathetically low. Our next step, therefore, was to find out whether or not we were wrong in our belief that from 20 to 25 per cent rather than from 4 to 5 per cent was a far more proper proportion of those patients with active tuberculosis who needed and who should have been given the opportunity of receiving help by means of some operative procedure. Information on this subject is not found in textbooks but is to be obtained only by means of detailed personal investigation. We felt that if we could get the ideas of the various well known tuberculosis groups in this country, such as those at Saranac Lake and Liberty, N. Y., Asheville, N. C., Rutland, Mass., Colorado Springs, Colo., Portland, Ore., and Los Angeles, it would at least give us a fair idea on which to base our estimate. In

Table 3.—*Number and Percentage of Cases of Pneumothorax, Phrenicectomy or Thoracoplasty Performed During 1930 in Each of the New England States*

| | Number | Per Cent |
|---|---|---|
| Connecticut | 276 | 6.6 |
| Maine | 33 | 1.7 |
| Massachusetts | 556 | 4.5 |
| New Hampshire | 4 | 0.3 |
| Rhode Island | 40 | 2.0 |
| Vermont | 20 | 1.0 |
| Total | 928 | 4.2 |

addition to such sources of information, we communicated with other well known tuberculosis and lung specialists all over the country as well as with the superintendents and directors of many state, municipal and government tuberculosis hospitals and sanatoriums where we knew that this method of treatment was carried on. In each case we asked, first, what proportion of tuberculous patients received some form of compression treatment and, secondly, an opinion as to what this percentage in general should be regardless of the figures of their particular institution. Each one to whom we wrote seemed to feel that the subject was a most important one. With only one or two exceptions the majority were of the opinion that compression or collapse therapy in some form should be done far more frequently than is now the case.

Dr. Alexius Forster of the Cragmor Sanatorium of Colorado Springs stated: "In my judgment, approximately 30 per cent of the cases we have here are eligible for some form of surgical help." Dr. F. M. Pottenger of Monrovia, Calif., and Drs. Ralph and Ray Matson of Portland, Ore., are more conservative and, while not committing themselves definitely, gave us the impression that 15 per cent or thereabouts of all their cases were suitable for some form of compression therapy. Dr. Jamie Dickie of Southern Pines, N. C., makes the significant statement that "with few exceptions, every terminal case of tuberculosis was at one time a suitable case for one of these three operations." His own percentage during the past two years has not fallen below 20 nor above 30. The figures of Dr. Henry D. Chadwick, late of Massachusetts and now of Detroit, are most striking. In the hospitals and sanatoriums under his direct supervision with a total of 1,326 patients, 57 per cent received some form of compression or collapse therapy. This is certainly an amazing figure when compared with the 4.2 per cent of the New England states. Dr. Bayard Crane of Rutland, Mass., places his figure at 30 per cent of the total number of patients admitted, while Dr. David Lyman of Wallingford, Conn., states that 47 per cent of the 177 patients in 1930 were so treated. He adds that if he had more facilities for bed care his figure would be well over 50 per cent.

The Saranac Lake figures, as given by Dr. Fred Heise at the Trudeau Sanatorium and those in private practice under the care of such men as Dr. Lawrason Brown, J. Woods Price and Edward N. Packard, apparently run from 40 to 50 per cent of some form of operative collapse treatment. It hardly seems necessary to go further.

In addition to this, other authoritative opinions were obtained from the literature on the subject. Dr. E. J. O'Brien[1] of Detroit is of the opinion that practically every patient with unilateral tuberculosis should be given some form of compression therapy. In uncontrollable hemorrhage, even in bilateral lesions, if a pneumothorax is not possible, phrenicectomy should be done on the side on which the bleeding occurs.

Drs. Jerome R. Head and O. C. Schlack[2] speak in no uncertain terms on this subject:

> For the past eighteen months at the Oak Forest Tuberculosis Hospital [which is the Cook County Tuberculosis Hospital of Chicago] we have been proceeding upon the principle that every case of unilateral pulmonary tuberculosis should be treated surgically, i. e., by some form of compression treatment. Our reasons for adopting this program have been based partly upon logic and partly upon experience. Not the least consideration has been a recognition of the type of patient with which we have to deal. The patients are drawn principally from the laboring classes of a large metropolitan area. A great many of them leave the hospital against advice after too short a stay, and even those who remain until discharged as arrested are unable on account of economic necessity to continue their convalescence at home under proper conditions.

Out of a mass of figures and percentages, some of which we have given here, we have come to the conclusion that 30 per cent was the figure that nearest represented the consensus of all these authorities. It certainly agrees with our own opinions on this subject. This is in sharp contrast with the 4.2 per cent which apparently holds true in New England. Were this figure, 30 per cent, applied to the six New England states, over 6,500 patients instead of 928 would have been given the benefit of pneumothorax or some similar treatment. It is not difficult to figure how many lives would have been saved thereby and how much unhappiness and invalidism prevented.

Granted, then, that it is the consensus among authorities in tuberculosis work that 30 per cent of all active cases of tuberculosis should receive some form of surgical compression treatment, how can it best be brought about that such a low figure, 4.2 per cent, as is found in the New England states, can be changed for the better? It is certainly evident that an educational campaign along this line is urgently needed among both the medical profession and the public. It is undoubtedly true that one reason for the low figure in New England is the refusal of many patients to consider what they believe to be radical and even experimental treatment. But this does not explain the 30 or even 50 per cent of such cases elsewhere. In our own work we have little or no difficulty in persuading a patient that pneumothorax should be tried, although it often takes time, patience and tact. On the whole we believe that it is the medical profession that is at fault, chiefly because the vast majority of physicians are not aware of the almost miraculous results that can be accomplished by this means even under the most discouraging and hopeless conditions. The general practitioner is well able to handle his anemia patients with liver and liver extracts and his diabetic patients with insulin. But because few practitioners are equipped to handle pneumothorax cases, they rarely recommend it. Thus the opportunity is lost. Those patients are indeed fortunate who are at once sent to a sanatorium where this treatment is given. Back of all this is the fact that to most of the medical profession tuberculosis is a dull and uninteresting disease and its treatment equally so.

What is the answer? The figures presented are not complimentary to New England. However, we do not doubt that a similar state of affairs would be shown elsewhere, at least outside the well known resorts for the tuberculous.

### CONCLUSIONS

1. Tuberculosis and its diagnosis and treatment should be given distinctly more attention in medical schools than is now the case.

2. Every general hospital, large or small, should freely and willingly admit tuberculous patients for study, diagnosis and operative treatment, if necessary. This one of us (J. B. H.) has again and again emphasized. Further, each general hospital should have on

its consulting staff at least, which in every case could easily be arranged, some one who could speak and act with authority in such matters.

3. Every tuberculosis hospital and sanatorium should have an x-ray plant or easy access to one and should be otherwise equipped to carry on compression treatment, while of course, most important of all, the members of its staff should be trained in the selection of cases and in the technic of pneumothorax. Phrenicectomy and thoracoplastic operations of course require the services of a surgeon trained in thoracic surgery.

4. The subject is of such real importance that it should form part of the yearly program of every county and local medical society. We have attended many meetings where such matters were discussed but either they were for a selected group of men engaged in this work or, if for the general medical public, of such a technical and detailed nature as to be practically devoid of interest and value.

5. We feel that the superintendents of tuberculosis hospitals and sanatoriums should not only write and publish articles on this subject but invite and urge the local medical profession to attend meetings where clinical demonstrations could be held and the whole subject of the modern treatment of tuberculosis presented in a simple and practical way.

# TRICHINIASIS

## REPORT OF AN OUTBREAK CAUSED BY EATING TRICHINOUS BEAR MEAT IN THE FORM OF "JERKY"

ALBERT T. WALKER, M.D.
Lieutenant (Junior Grade), Medical Corps, U. S. Navy
MARE ISLAND, CALIF.

Although lower animals are the normal hosts for Trichinella spiralis, man may be accidentally infected by eating insufficiently cooked or raw trichinous meat. By trichinous meat is meant meat in which the larvae of Trichinella spiralis have become encysted and require only liberation from their cystic cells, during the process of digestion, to resume their cycle of development and in turn infect their latest host. It has been said[1] that encysted larvae can remain alive in muscle tissue for as long as thirty years. When meat containing cysts is eaten, the wall is digested, the larvae are liberated, and the cycle once more is started. Briefly, this cycle consists in the liberation of the embryos from the cyst; their passage into the small intestine, where they grow to maturity in two or three days; the fertilization of the female by the male; the burrowing of the anterior end of the fertilized female about the sixth to the eighth day into the intestinal mucosa; the escape of the embryos from the vulva of the female into the intestinal mucosa over a period of about six weeks; the passage of the embryos into the lymph spaces of the mucosa and submucosa, and the passage of the embryos through the right side of the heart by way of the blood stream, through the lungs to the general circulation and thence to striated muscle, which they actively penetrate. Here the embryos rapidly develop to the adult stage in about fifteen days, at which time the first step in encystment takes place. When the worms implanted in the muscle tissue are seen early, they lie flat and in the plane of the muscle fibers, but after reaching maturity they begin to curl at both ends and encystment is under way about one month after infection. Encystment is probably complete by the end of the twelfth week for a given worm, the actual time of encystment after eating trichinous meat depending on the date of birth of the embryos after the burrowing of the female into the intestinal wall. From the foregoing, one can see that the eating or even the chewing and rejecting of trichinous meat starts the cycle of development which ends in the encystment of the organisms in the muscles of the host. Classically, pork is the offending meat, but other edible animals also act as host, possibly from eating trichinous rats and pigs. In the outbreak reported here the brown bear was the cause of infection.

### REPORT OF CIRCUMSTANCES SURROUNDING AN OUTBREAK IN VALLEJO, CALIF.

Case 1.—Lloyd K., aged 18 years, joined a party of hunters in Trinity County, Calif., and brought down a brown bear weighing about 400 pounds (180 Kg.), age not determined. The bear was skinned, and as there was a large amount of meat to be disposed of, it was decided to "jerk" it and keep it for later consumption. The process of "jerking" consists in cutting the meat in strips, then smoking and drying it in the sun for a few days. The end-result is a strip of black meat 18 inches long, 2 inches wide, and one-half inch thick, rather tough and leathery and not particularly palatable. The meat was divided among the members of the hunting party; Lloyd K. brought his home and proudly passed it around at school as well as at home and among the neighbors.

About seven days after eating his first jerky, he became ill with nausea, vomiting, diarrhea and generalized pain in the abdomen, which lasted two or three days and subsided. He continued to chew the jerky at odd times over a period of several days, and three or four days later he became ill with fever, malaise, anorexia, prostration and pain and stiffness in the muscles of the gastrocnemius groups. He continued to get worse; the muscular pains became quite severe; the temperature was high with large daily swings; he was unable to move his limbs, and he rapidly became delirious. On the evening of October 12, fourteen days after the onset of his illness and about twenty-one or twenty-two days after first eating the jerky, he was seen by me.

He was lying in bed, delirious, rambling in his talk, cyanotic, toxic and dehydrated. He responded meagerly to questions but did not give an intelligible reply. His temperature was 96 F. by mouth; pulse, 148, weak and thready. The pupils were dilated and did not react to light. The lips were parched and cyanotic; swallowing appeared difficult but there was no regurgitation of fluid through the nose when given a small amount of water with a drinking tube. There was some stiffness of the muscles of the neck, but I was unable to determine whether this was definite rigidity or merely resistance to my efforts to flex his head on his chest. His breathing was labored and of a peculiar character: it was not the labored breathing of embarrassed respiration due to fluid or cardiac insufficiency, but rather it gave the impression of being due to muscular insufficiency. The respiratory rate was 20. The abdomen was flat and flaccid; there was no tympanites, rigidity or guarding. He was unable to move his legs and could not cooperate in the examination. A superficial examination of the reflexes revealed: biceps, absent; patellar, absent; abdominal and cremasteric, absent. A leukocyte count made at this time showed 42,000 white cells with 97 per cent polymorphonuclears. The urine was dark, thick and acid, with a specific gravity of 1.030; albumin was 2 plus; it was negative for sugar. It was loaded with coarse and fine granular casts, from 250 to 300 per high power field. There were many leukocytes. Urine cultures on Endo's and litmus lactose plates showed no pathogenic bacteria. The boy died at 6 o'clock on

---

Read at a staff conference, United States Naval Hospital, Mare Island, Calif.

From the outpatient service of the United States Naval Hospital, Dr. E. E. Curtis, chief of service.

[1] Whitmore, E. R.: Trichiniasis, in Tice: Practice of Medicine, Hagerstown, Md., W. F. Prior Company, Inc. 5:175.

the morning of October 13, a few hours after I had first seen him. A necropsy was requested and permission granted.

A series of cultures both aerobic and anaerobic were made at autopsy; the spinal fluid, mesenteric glands and the intestinal contents were negative for pathologic change in the viscera.

Sections of the bear meat were so tough that they had to be soaked for twelve hours before the microtome knife could make satisfactory sections. When stained and examined, they were found to be loaded with Trichinella spiralis in the encysted stage.

A necropsy was performed at 2 p. m., October 13, by Dr. H. E. Ragle, Lieutenant Commander, Medical Corps, U. S. Navy, who made the following observations:

The body was well developed and fairly well nourished. The skin was clear and somewhat brown. There were no signs of edema. The teeth were good. The pupils were equal in middilatation. A Y-shaped incision was made at necropsy. The muscles were well developed. There was very little subcutaneous fat. The lungs were partially collapsed and free from pleural adhesions. The cut sections showed no edema, congestion or consolidation. There was no excess of pleural fluid in the pleural cavities. The pericardial sac contained 100 cc. of clear straw-colored fluid. The heart was normal in size; the musculature was good and the valves were normal. The right side was somewhat dilated by blood. There was no free fluid in the peritoneal cavity. The lower edge of the greater curvature of the stomach adhered to the posterior parietal peritoneum. Some adhesions were found between the gallbladder and the loops of duodenum and jejunum. There was no gas in the intestinal tract. The mucosa of the intestinal tract showed a marked hyperemia throughout. The entire chain of mesenteric glands were enlarged and red. The spleen was normal in size and slightly congested. The liver was normal in size; a cut section showed a fat necrosis. The pancreas was normal. The gallbladder was normal. The kidneys were slightly swollen. The capsules stripped fairly easily. A cut section showed an acute congestion. The markings were good. The urinary bladder was distended by rather dark urine. The suprarenals were normal. The prostate was normal. The spinal fluid, obtained by cistern puncture, was clear; a stained smear showed it to be free of organisms and excess cells. The calvarium was removed; the brain was somewhat edematous and the capillaries were engorged. The meninges were normal. On histopathologic section, the unencysted form of Trichinella spiralis was found throughout the pectoral muscles and the diaphragm.

Sections of the bear meat showed encysted Trichinella spiralis.

The anatomic diagnosis was: edema of the brain; fat necrosis of the liver; acute nephritis; acute enteritis with enlargement of the mesenteric lymph nodes, and intestinal adhesions (old).

The microscopic diagnosis of the pectoral muscles and of the diaphragm was trichinosis.

The rest of the patient's family were lightly infected, except one sister, Lorraine K. Their histories were briefly as follows:

Case 2.—Mrs. K., aged 38, chewed only a small piece of the jerky, about September 23 or 24, and became ill, October 2, with headache, pain in the back and legs, and chills followed by fever, which rose quite high in the afternoon. She continued feeling bad, with fever in the afternoon and evenings and morning remissions, and severe pain in the gastrocnemii, but there was no nausea, vomiting, or diarrhea. When seen by me the evening of October 12, she had been sick ten days but was feeling much better, although quite weak, and was still having pain in her legs and back. The temperature was 99 F.; pulse, 80. Physical examination was negative except for sluggish biceps and patellar reflexes.

Case 3.—Mr. K., aged 42, ate only two or three small pieces of jerky, September 20, and became ill on October 3, thirteen days after eating the meat. His eyes became bloodshot and "looked as though they were going to pop out of his head." He also had chills and fever and a moderately severe headache. There was no nausea, vomiting or diarrhea, but the patient said that he had daily swings of fever, feeling fine in the mornings and hot and flushed in the afternoons and evenings. October 11, the day before I saw him, he began to improve and stated that he felt fine. At no time had he had any muscular pains. October 16, the urine showed a trace of albumin, from 20 to 30 coarse granular casts per high power field, and many leukocytes. The same day he had an eosinophilia of 31 per cent.

Case 4.—C. K., a girl, aged 15, developed a headache on October 8 and went to bed on the ninth. At first she stated that she had not eaten the bear meat but on close questioning admitted that on September 20 she had chewed a small piece, but after a few moments of chewing she did not swallow it. Since going to bed, October 9, she had had headaches, chills and a daily evening rise in temperature but at no time had there been any nausea and vomiting. When seen by me on the evening of October 12, three days after she went to bed, she was feeling tired and had pain in the thighs and the upper arms. The temperature was 101 F.; pulse, 92. Physical examination was negative except for sluggish biceps and patellar reflexes and tenderness to palpation over the muscles of her thighs and of the deltoid region. The urine showed no albumin or casts. October 15, she had an eosinophilia of 39 per cent.

Case 5.—Lorraine K., aged 18 years, ate several pieces of bear jerky, September 20, but did not notice any symptoms until fourteen days later, October 4, when she went to bed with a headache, chills and fever. There was no nausea, vomiting or diarrhea. After the onset of the initial symptoms she began to have muscle pains throughout her whole body but especially in her legs, shoulders and back. When first seen, she was lying in bed acutely ill with a temperature of 104.6 F., a pulse rate of 120, and respiration 20. She said that she was unable to move her legs without severe pain. She had some dysphagia and complained of burning in her throat on swallowing. Her eyelids were edematous; subconjunctival hemorrhages rimmed the iris of each eye; the pupils reacted to light sluggishly. Questions had to be repeated; there appeared to be some deafness. She complained of some stiffness of the neck—Kernig's sign was positive. Her breathing was labored and of the same character as was that of her brother's; the accessory muscles of respiration were apparently functioning by voluntary effort. The lung fields were clear. The abdomen was flat, with no tenderness; there was some tenderness and swelling of the muscles of the left flank and there was a local elevation of temperature as compared with the corresponding side. Her ankles were thick, but there was some pitting edema over the dorsum of the feet and of the ankles. A superficial neurologic examination showed sluggish and weak deep reflexes; superficial reflexes were present but weak. Examination of the blood, October 12, revealed: white blood cells, 21,000; polymorphonuclears, 97 per cent; eosinophils, 1 per cent. The specific gravity of the urine was 1.028. The urine was cloudy and amber colored; it was acid and contained a few leukocytes and epithelial cells. Throat cultures showed a long chain streptococcus; stools were negative for ova and parasites. Cultures of the feces showed no pathogenic organisms. Blood cultures were negative. Laboratory examination, October 15 revealed: a trace of albumin in the urine; from 250 to 300 granular casts per high power field; white blood cells, 18,000; polymorphonuclears, 92 per cent; eosinophils, 2 per cent; lymphocytes, 5 per cent. October 16: white blood cells, 20,400; polymorphonuclears, 80 per cent; eosinophils, 12 per cent. Daily urine examinations were made and on October 22 albumin was negative, and there were no casts and only a few leukocytes. A stained catheterized specimen showed numerous B. coli. Urine cultures, October 23, showed a heavy growth of B. coli.

### PROGRESS

Mr. K., Mrs. K. and C. K., in from seven to ten days, lost their fever and muscular pains and were allowed up and about the house. Lorraine K. had a rather stormy course; her temperature ranged from 96 F. to as high as 105.4 within four hours and her pulse from 110 to 140 and on one occasion to 150 per minute. On one occasion, her temperature rose to 104.8; her flanks became distended and were exquisitely tender to the lightest palpation; this was considered to be an acute local myositis due to showering of worms into these muscles. Throughout the course of the illness the kidney complication coupled with cardiac embarrassment and fatigue caused the greatest concern. These, however, responded to careful nursing and systematic treatment. Because of the severity of her infection and resultant toxic manifestations it was found necessary to keep her circulation well supported and elimination active.

### TREATMENT

There is no specific treatment for trichinous infection. These cases were all treated symptomatically. Lloyd K. was so toxic and dehydrated when I saw him that he died a few hours later. The other members of the family were given daily purges with magnesium sulphate; the urine was kept alkaline with sodium citrate in large doses, and after the severe symptoms incident to the stage of muscle invasion had passed, thymol in olive oil was given intramuscularly, from 0.13 to 0.3 Gm. a day for several days. During this period of treatment the urine was watched carefully, and, although occasionally granular casts were found, this was not considered a contraindication to treatment. In addition to this, thymol was given by mouth, 1 Gm. in a single dose repeated in twenty-four hours after a twenty-four hour fast and after a purge with saline solution. Although I have no accurate method of determining the rate or degree of improvement following the treatment, I use the eosinophilia in the differential blood count as an index of the degree of involvement and of the amount of improvement when compared with counts made before the treatment was instituted, but after the acute typhoid-like symptoms had subsided. When first seen, Lorraine K. was given 1,000 cc. of saline solution by hypodermoclysis to combat the evident dehydration, and then retention enemas of 500 cc. of warm tap water were given every four hours. When her temperature dropped to 96 and below, warm enemas of whisky and tincture of digitalis intramuscularly were given to combat collapse.

The toxic nephritis with from 200 to 300 granular casts per high power field was treated by alkalization with sodium citrate, intramuscular injections of calcium gluconate and tincture of digitalis intramuscularly for her failing circulation. Hot packs were used to relieve the acute pain of the myositis during the stage of dissemination and acetylsalicylic acid and codeine were given for pain, with occasionally 0.015 Gm. morphine sulphate when the acetylsalicylic acid and codeine failed to give relief.

### COMMENT

On the evening of October 12, the problem confronting me resolved itself about the fact that all five members of a family had been taken acutely ill over a period of a week. The various members had been ill for from four to fourteen days, with a diagnosis of probable typhoid. The only possible common source of infection was some "jerky" bear meat of which they had all partaken in large or small amount. So far as could be determined, they had not all partaken of any other food which could be held under suspicion. On the strength of this and the clinical manifestations of a typhoid-like fever, accompanied by a soreness of the muscles, edema of the eyes, and sluggish or absent reflexes, a tentative diagnosis of trichinosis was made. It was decided that the diagnosis could be finally made only in the laboratory, so complete laboratory studies were instituted at once. The following morning at 6 o'clock one member of the family (Lloyd K.) died, and a necropsy was held, but a definite diagnosis was not established. Sections of the suspected "jerky" bear meat were run through that day and Trichinella spiralis was found in large numbers. The striking features of the clinical picture in these cases was the great prostration noted even in those who had eaten small amounts of the infected meat. All but one of the patients complained of muscular pains, only one had the characteristic edema of the eyelids, and only one had subconjunctival hemorrhages. During the early stages of the disease, when the typhoid-like symptoms were so prominent, there was a decided polymorphonuclear reaction; but as dissemination neared completion and encystment commenced, the characteristic eosinophilia began to appear and reached 39 per cent in one of the patients. Lloyd K., even a few hours before death, with a white count of 42,000, showed no eosinophilia.

This outbreak presented some unusual aspects from a public health standpoint. A bear is a large animal and "jerky" goes a long way. On close inquiry it was found that not less than twenty-five people in this immediate vicinity had eaten the jerky, and a large portion of it had been left at the scene of the hunt with residents of that district. In addition, one member of the party took his share home to a nearby large city and treated his friends, so that in all probably fifty or more people ate "jerky" from this trichinous bear before they could be notified through the state board of health that the meat was dangerously unfit for consumption.

### SUMMARY

An outbreak of human trichiniasis with one death occurred following the ingestion of trichinous bear meat in the form of "jerky." The encysted trichinellae were found in sections made from the bear meat and also were recovered from muscular tissue of the diaphragm and pectorals at the necropsy of the patient who died of the effects of the disease. The outstanding clinical features of the case were the typhoid-like symptoms, chills and fever, a high leukocyte count with marked polymorphonuclear reaction during the height of the disease, the absence of muscular pain in one of the five patients, edema of the eyes in only two of the five, and the occurrence of the characteristic eosinophilia only during the period of convalescence.

---

**The Scope of Clinical Medicine.**—Pope has said that the "proper study of mankind is man," and even though the clinician has science, art and craftsmanship, unless he is intensely interested in human beings he is not likely to be a good doctor. At bottom, we all have many qualities in common, and these fundamental properties can be observed with somewhat less effort on our part in the clientele of a hospital, than in those members of society who are more deeply imbued with the "herd instinct," as Trotter calls it, or are protected by inherited conventionalities of thought and conduct. If we turn our attention for an instant from the study of the abnormal organ or pathology to the study of the morbid patient as a whole, the scope of clinical medicine widens and takes on a character that differentiates it from all other arts and sciences.—Longcope, W. T.: Methods and Medicine, *Bull. Johns Hopkins Hosp.* **50**:4 (Jan.) 1932.

## EPISCLERITIS DUE TO ALLERGY

Ray M. Balyeat, M.D.
Associate Professor of Medicine and Lecturer on Diseases Due to Allergy, University of Oklahoma School of Medicine
and
Herbert J. Rinkel, M.D., Oklahoma City

After a careful search for the etiology of episcleritis by the most thorough investigators,[1] we have concluded that many cases must be reported as "cause unknown." The fact that a specific hypersensitiveness might often be the etiologic factor in patients suffering from episcleritis of the so-called idiopathic type was suggested by the following case.

### REPORT OF CASE

F. S., a physician, aged 37, said that for ten or twelve years he had suffered every five or six months from eye symptoms characterized by a fairly sudden onset of photophobia, lacrimation and painful eyeballs. The duration of the attacks was from seven to fourteen days. We have never seen him with symptoms. However, he reports that while in school in the East he was studied by a number of ophthalmologists, all of whom made the same diagnosis; namely, episcleritis of unknown origin. His practice of medicine has been seriously interfered with during the last five years, as for at least thirty days out of the year the severity of symptoms would necessitate his discontinuance of work. Between the attacks he has never had eye symptoms except during the early fall of the year, at which time he has suffered from seasonal hay fever.

He was first seen by us in 1927, at which time he gave a history of seasonal hay fever of twelve years' duration and an occasional attack of urticaria. At this time we were not testing seasonal hay fever patients in a routine manner with food allergens. He was found sensitive to the following pollens:

| | | | |
|---|---|---|---|
| Giant ragweed | +++ | Spiny amaranth | ++ |
| Short ragweed | ++++ | Western water hemp | +++ |
| Western ragweed | ++ | | |

Preseason pollen therapy was instituted, both the ragweed and the pigweed group being employed, with only fair results. He was again desensitized in 1928, the same pollen antigens being used, with fair results. The following year he came in for general rechecking, at which time he was tested with pollens, animal epithelia, dusts of all kinds, and foods. He was found sensitive to the following:

| | | | |
|---|---|---|---|
| Giant ragweed | ++++ | Lima bean | +++ |
| Short ragweed | +++ | Buckwheat | ++ |
| Western ragweed | +++ | Pecan | ++ |
| Spiny amaranth | +++ | Strawberry | ++ |
| Western water hemp | +++ | Lettuce | +++ |
| Pyrethrum | ++ | Celery | +++ |
| Duck feathers | ++ | Watermelon | +++ |
| Goose feathers | ++++ | Navy bean | +++ |
| Chicken feathers | ++ | Cucumber | ++ |
| | | Sweet potato | ++ |

Hay fever treatment was again instituted, the same pollen groups that were previously used being employed. He was also carefully advised concerning the possibility of feathers as a secondary factor in seasonal hay fever. Foods to which he was specifically sensitive were removed from the diet. The result of pollen therapy this season was nearly 100 per cent.

The part of the history in which we are chiefly interested just now is the fact that during the past year he has not suffered recurrent attacks of episcleritis except on one occasion, about two weeks following the time he was advised concerning his diet, when he deliberately ate some of the foods to which he is specifically sensitive.

We have insisted that he again eat the foods which we advised to be removed from his diet, to see whether symptoms of episcleritis would recur, but he reported: "There has been no return of the episcleritis which has dealt me so much misery during the last ten years. I am convinced it was due to food allergy and do not want to run the risk of having another attack."

### COMMENT

The case we have just reported is typical of the type that May[1] describes as periodic transient episcleritis. The patient had been studied by a number of competent ophthalmologists and internists, and there was no disagreement about the diagnosis of the chain of symptoms with which he suffered. The internists were unable to find any possible foci of infection that might produce his trouble. In a survey of the literature, allergy is not mentioned as one of the possible causes of episcleritis. In our patient no change was made in his routine life except that his feather pillows were covered with rubberized sheeting, and the foods to which he was specifically sensitive were removed from his diet, with the result that he has been free from symptoms for over a year, except on one occasion when he deliberately partook of foods to which he is specifically sensitive.

The fact that a patient with episcleritis has not suffered or does not suffer from some well recognized allergic syndrome, such as hay fever or hives, as our patient did, by no means rules out the possibility of allergy as an etiologic factor. It is a well recognized fact that one may become specifically sensitive to foods or other substances and the manifestation of sensitivity occur in only one tissue of the body; for example, the brain, the skin or the nasal, bronchial, intestinal or bladder mucosa. In discussing this case and the subject of episcleritis in general, Dr. Edward Jackson[2] of Denver said that his study of episcleritis during the last decade has impressed him with the possibility of allergy as an etiologic factor, but that he had never had an opportunity to study any case from an allergic standpoint.

On the basis of the data given, it seemed justifiable to suspect an allergic factor in the etiology of the symptoms of episcleritis with which our patient suffered.

## CLINICAL FEATURES OF VITAMIN A DEFICIENCY

GEORGE B. EUSTERMAN, M.D.
and
DWIGHT L. WILBUR, M.D.
ROCHESTER, MINN.

[Editorial Note.—The following article is one of a series on the Present Status of the Knowledge of Vitamins, prepared under the auspices of a committee composed of Morris Fishbein, chairman, Lafayette B. Mendel and Julius Hess, representing a joint committee of the Council on Pharmacy and Chemistry and the Committee on Foods. These articles have been considered by the Council on Pharmacy and Chemistry and by the Committee on Foods and are published under their auspices. The opinions expressed are those of the authors and not necessarily the opinions of the Council on Pharmacy and Chemistry or the Committee on Foods.]

The peculiar curative virtues of certain foods have been recorded at isolated periods since ancient times. Some of these observations are strikingly accurate and prophetic. Today, from the standpoint both of human experience and of laboratory research, it has been definitely proved that a natural food supply furnishes, and normal nutrition requires, other substances in addition to proteins, fats, carbohydrates, water and salts. Present knowledge concerning these accessory food factors, or vitamins, is rather the product of development than of any isolated discovery, and much of this development antedates the introduction of the word "vitamin." It is almost exclusively within the last quarter of a century that experimental investigation, to which American scientists have made numerous and valuable contributions, has, in addition to making fundamental discoveries, explained the rationale of such historic dietotherapeutic procedures, as, for example, the use of fresh vegetables and citrus fruits in the treatment of scurvy and of cod liver oil in rickets, the feeding of liver in night blindness, and the substitution of barley for polished rice in beriberi.

[2] Jackson, Edward: Personal communication to the author.

From the Division of Medicine, the Mayo Clinic.

The conception of the fat-soluble vitamin A arose from the failure of McCollum and Davis[1] and of Osborne and Mendel[2] to secure normal growth of experimental animals for a long period of time on purified foods furnishing adequate proteins, fats, carbohydrates and salts, whereas the conception of the presence in certain foods of the water-soluble vitamins B and C developed primarily from observations on disease.

Until recently the versatility of vitamin A has apparently not been appreciated. A remarkably increasing literature in the last year or two attests its growing importance in the chemistry of food and nutrition, not only in the prevention and cure of certain ailments of man but, when supplied in liberal proportion, in the maintenance of a satisfactory state of nutrition and a high degree of health and vigor, both in the growing child and in the adult.

### HISTORICAL SUMMARY

The most readily appreciated clinical symptoms of vitamin A deficiency have to do with changes occurring in the eyes. It has been known for centuries that some relationship between ocular conditions and states of malnutrition existed. Hippocrates is quoted as advocating an abundance of liver, or liver and honey, in cases of night blindness, and such treatment is recognized as scientifically correct today in cases of hemeralopia (night blindness) on a nutritive basis.

McCollum and Simmonds[3] stated that Livingstone, in 1857, describing the hardships endured in his explorations in Africa, related that his party while suffering from exposure to the weather lived for a time on sugarless coffee, manioc roots and meal, and reported that "the eyes became affected (as in the case of animals fed, on experiment, on pure gluten or starch)." Unfortunately, the experiments referred to have not been found described. On the continent of South America, Gama Lobo,[4] in 1865, described a disease of the eyes among the poorly nourished slaves on the coffee plantations of Brazil. This was the so-called ophthalmia Brasiliana, and seventeen years later his fellow countryman de Gouvêa[5] gave a description of the real picture in xerosis of the conjunctiva, hemeralopia, and destruction of the cornea in nutritional disease. Bitôt,[6] in 1863, had recognized the clinical relationship between xerosis of the conjunctiva and certain kinds of night blindness of human beings, and first described the former condition. Endemic night blindness among orthodox Russians during lenten fasts was described (1887). During such periods, starvation among adults was common, and it was observed that nurslings whose mothers practiced long religious fasts not uncommonly had spontaneous sloughing of the cornea.

Among the first descriptions of nutritional keratomalacia in the United States were those of Little,[7] Weeks[8] and Kollock.[9] The most extensive early report of a large series of such cases came from still another continent, Asia, with the description by Mori[10] of 1,400 cases of xerophthalmia among children in Japan, a syndrome known as "hikan."

It is rather interesting that there were few accurate early descriptions of such diseases in Europe, but the unique experiences which have occurred in Denmark within the last two decades, chiefly those of Bloch[11] and Blegvad,[12] have been outstanding in producing clinical data to correlate with the extremely numerous and accurate experimental data which have been collected during this same period. It was shortly after the beginning of their studies that Osborne and Mendel, and McCollum and Davis, showed experimentally that young animals fed on food mixtures alike in all other respects would continue to grow and thrive or would soon cease growing and shortly thereafter sicken and die, according as the fat in these mixtures was butter fat, cod liver oil, egg yolk or lard.

In 1919, Bloch unwittingly performed a human experiment corresponding exactly to feeding experiments on animals, by dividing into two groups thirty-two healthy children, from 1 to 4 years of age, in an institution in Copenhagen, one group receiving whole milk and the other fat or vegetable fat in margarine. In eight cases among those on the vegetable-fat diets, xerosis developed and was subsequently relieved by cod liver oil, whereas in the group given whole milk no disturbance developed. This close correlation was further demonstrated in Denmark during and after the war, for, as Widmark[13] has shown, the number of cases of xerophthalmia in that country (from 1914 to 1920) was inversely proportional to the amount of butter fat consumed by the people.

### THE NATURE, PHYSIOLOGY AND SOURCES OF VITAMIN A

Investigations based on Steenbock's[14] discovery in 1919 that among the vegetable foods the distribution of vitamin A is associated in a remarkable way with yellow pigmentation have borne much fruit. The yellow pigment carotene is apparently the plant source of the vitamin A of animal tissue. In fact, biologic tests alone, according to the work of Capper, McKibbin and Prentice,[15] cannot distinguish between carotene and vitamin A, and it would seem probable that this vitamin is a product of conversion by animals and ultimately owes its origin entirely to carotene. The physiologic potency of pure carotene has been shown by various investigators to be as striking as that of other known vitamins. The latest evidence[16] indicates that carotene is apparently unchanged in the bowel and is converted by hepatic enzymatic activity into vitamin A; the latter, a colorless product, is stored chiefly in the liver. This organ also undoubtedly plays an important part in the regulation of the concentration of the vitamin throughout the remainder of the body. Because of the very small amounts of carotene which will overcome vitamin A deficiency in the rat, it has been assumed that the vitamin may act chemically as a catalyst, but nothing is known of the mechanism of the physiologic action of the substance. The functions of vitamin A have been variously stated as growth promoting, infection resisting and antixerophthalmic, although it has been denied by some that this vitamin has any of these functions. The high vitamin A content of mother's breast milk has been determined by Macy, Outhouse, Graham and Long,[17] and is of tremendous importance to the nursling. It has been shown by Jennie Rowntree[18] that there is no alimentary vitaminuria in infants and young children following generous allowances of vitamin A in the diet. Establishment of this fact seems to signify that the limit of the capacity to store vitamin A is not easily reached. Loss of vitamin A in the feces is variable and occurs independent of the intake, according to Rowntree's investigations.

The usual food sources of vitamin A are milk, butter, eggs and green vegetables. As these are representative of the more expensive foods, their consumption is frequently inadequate among the poor, especially during periods of economic depression, war, famine or drought. Lard, vegetable fats and oils, as a general rule, do not contain vitamin A. On the other hand, certain animal oils, for example, cod liver oil, and probably halibut liver oil, are very rich in it. The vitamin A content of these products is dependent on the diet of the animal and is influenced by the reserve store in the body. Carrots, the yellow tissue of pumpkin, tomatoes, sweet potatoes and green dried peas also contain appreciable amounts of carotene. Cereals and muscle tissue are poor in it. Sherman and Smith[19] have tabulated the results of various investigators as regards the vitamin A content of typical foods from a wide biologic range of sources.

## DISEASE AND PATHOLOGIC CHANGES AS A RESULT OF VITAMIN A DEFICIENCY

It may be said at the outset that the most familiar form of vitamin A deficiency, xerophthalmia, both of infants and of adults, especially the latter, is extremely rare in the United States. There is good reason to believe that the ordinary food supplies of the major portion of the population of this country furnish enough of this accessory food factor so that there is no tangible evidence of a lack of it. States of vitamin A deficiency are less frequently observed in adults than in infants and young children because the storage of vitamin is greater in adults and there is no demand on storage depots for purposes of growth. Moreover, the adult instinctively looks for nourishment containing this vitamin. It is likely, however, that certain individuals, the poor in particular, do not consume enough foods that contain vitamin A and vitamin G to insure a state of nutrition essential to the greatest physical stamina, efficiency and ability to resist infectious diseases. As a result of the rarity of vitamin A deficiency disease in man, few clinical and pathologic observations have been made. This is in contrast to the numerous and exhaustive studies on experimental animals. The incidence of rachitic, pellagrous and scorbutic forms of avitaminosis is undoubtedly much greater than of those frank forms of avitaminosis due to vitamin A deficiency. The inadequate dietary of a nation like China or India, and the vicissitudes of war, famine, flood, drought and poverty in any country have, from time to time, made possible valuable clinical observations relative to states of vitamin A deficiency in man, which have, in the main, been corroborative of the results of experimentation on animals.

Previous to the differentiation of vitamins A and D from each other by McCollum and his co-workers[20] in 1922, many of the abnormalities reported following clinical observations and experimental studies, thought to be solely due to vitamin A deficiency, were really due to a deficiency either of vitamin A or D, or of both. Fortunately the factor of vitamin D deficiency was eventually shown to play only a secondary part in the diseases we are to consider.

Vitamin A deficiency disease may result from reduction of adequate intake of this vitamin, as the available food supply may be poor in it; from deficient absorption and storage as the result of intestinal or hepatic derangement or disease, or from an increased demand for, and consumption of, the vitamin; for example, during periods of rapid growth or of disease, especially severe infectious diseases, when the basal metabolic function may be greatly enhanced. These features may explain the development of avitaminosis in the presence of an apparently adequate supply of the vitamin.

In the light of present knowledge concerning the diseases and pathologic processes engendered through deficiency of vitamin A, it is essential that a broad view of the subject be taken and not, as in the past, that attention be concentrated chiefly on changes in the ocular organs. It is appropriate at this time to emphasize the fact that it is doubtful whether deficiency disease in man, with the possible exception of scurvy, ever occurs uncomplicated, for symptoms of uncomplicated deficiency disease in the animal occur only following a regimen of carefully planned experimental diets. This aspect of the subject is a plausible explanation for the controversy that still exists over certain clinical and pathologic phenomena in states of vitamin A deficiency.

The physician may gain a fairly clear conception of how vitamin A deficiency manifests itself clinically and pathologically in man by realizing that such deficiency affects epithelial tissues in a specific manner. The pathologic investigations of Wolbach and Howe,[21] subsequently confirmed by various other investigators, show that there is a substitution of stratified keratinizing epithelium for normal epithelium in various parts of the respiratory, alimentary and genito-urinary tracts, in the eyes and in the para-ocular glands; or, in brief, metaplasia of the greater part of the ectodermal leaf of the body. Such changes may be followed by infection in the various organs or tissues. Thus, the maintenance of intact, healthy epithelial membranes, which constitutes the first line of defense against bacterial invasion, is a prophylactic function of this vitamin of the first importance.

### EYES

It has been widely considered until recently that the eye was the only organ affected in vitamin A deficiency. The effects on the eye result in two types of changes: (1) hemeralopia, or night blindness, and (2) xerophthalmia, xerosis or keratomalacia, all of which have to do with changes in the epithelium of the eyeball and para-ocular glands.

*Night Blindness.*—Night blindness may be defined as difficulty or inability to adapt the faculty of vision to very faint illumination, and it may result from intra-ocular as well as from deficiency diseases. In the latter type, it is generally presumed that the hemeralopia is of the so-called essential type and that it depends on disturbance in the visual purple metabolism of the retinal rod cells, and changes in the ocular fundi are absent. Under ordinary circumstances of bright light, visual purple is bleached, but it is also being constantly regenerated. Experimental evidence indicates that there is a close relationship between vitamin A and the visual purple, since, as Fridericia and Holm[22] have shown, there is delay or failure in regeneration of visual purple in animals deprived of vitamin A. In addition, the high vitamin A content of the hog's retina has been demonstrated by Yudkin, Kriss and Smith,[23] so that it is possible that in the retina there may occur a reversible reaction, vitamin A being required for the production of visual purple and the latter, under suitable conditions, producing vitamin A. It is obvious that the manifestation of night blindness will occur chiefly after exposure of the patient to bright light, and it is in this way that the supply of visual purple is depleted in amount, and ample regeneration cannot occur. This was convincingly demonstrated by Aykroyd,[24] who found that after prolonged exposure to brilliant sunlight, with apparent rapid exhaustion of the visual purple, several cases of night blindness were first manifested. Night blindness may occur in association with other ocular lesions accompanying vitamin A deficiency.

*Xerophthalmic Changes.*—Pillat,[25] whose extensive observations in China on the ocular changes in vitamin A deficiency of adults have given him an unparalleled experience, divides the symptoms of these changes into the following groups: (1) night blindness, (2) xerosis epithelialis conjunctivae, (3) xerosis epithelialis corneae, (4) keratomalacia, (5) pigmentation of the cornea, (6) meibomitis, (7) blepharitis and hordeolum, (8) decrease of tear fluid, (9) edema and puffiness of the lids, and (10) comedones. Xerosis, or dryness of the conjunctiva, Pillat considers to be the usual second stage of vitamin A deficiency. It manifests itself in four forms: Bitôt's spots, irregular xerosis, loss of luster, and wrinkling of the bulbar conjunctiva. Of these, Bitôt's spots, consisting or triangular white spots appearing like dense foam of soap in the palpebral fissure, with the base at the limbus, are perhaps best known and are produced by hyalinization and degeneration of the upper conjunctival layers, with exfoliation. Xerosis of the cornea is the next stage, and almost always coexists with conjunctival xerosis. Associated inactivity of the para-ocular glands, with lessened secretion of tears, frequently accompanies these changes.

Pillat considered keratomalacia the last stage of vitamin A deficiency in the eyes of adults. When corneal softening occurs, infection begins, distorting the primary picture and resulting in severe complications which frequently lead to complete or partial blindness.

Conjunctival pigmentation is one of the most characteristic changes, as described by Pillat, Wright[26] and Mori. The pigment is light brown and probably melanotic, and may have the appearance of intensive argyrosis. John[27] has demonstrated that the sensibility of the cornea, in advanced stages of the condition, is reduced to a high degree, for instance up to 100 times, whereas the conjunctival sensibility is much less reduced, and such insensibility may remain months after disappearance of the local ocular condition. He believes that there is evidence of a lesion of the central nervous system in these deficiency diseases.

The ultimate result of vitamin A deficiency has not been settled, but Bloch[28] presented material which he studied over a considerable number of years, and he considered that "The death rate among children is considerable after their recovery from xerophthalmia; hardly two thirds of these children reach the age of 8 years. After this their development goes on normally." The deficiency leaves no characteristic defects unless impairment of vision, or blindness, persists.

### THE RESPIRATORY TRACT

The high susceptibility to infection of the respiratory organs of the rat and other experimental animals when deprived of an adequate amount of vitamin A seems to be borne out in man. Of eighty-six children with xerophthalmia, Bloch noted the presence of pneumonia in fifteen and bronchitis in twelve. Nasal and tracheobronchial catarrh was prevalent also. All the pulmonary complications were severe, and there was no improvement or cure until a sufficient intake of vitamin A was provided. In two of the four cases of nutritional keratomalacia in infants, reported by Ross,[29] bronchopneumonia was the immediate cause of death. Pillat observed that children usually succumb to the general disease on account of diarrhea and bronchopneumonia before the ocular symptoms become as distinct as in adults. To an inadequacy of vitamin A in the human dietary, McCarrison[30] has attributed the high incidence of infection of the nose and accessory sinuses, including otitis media, and of the upper respiratory passages and lung, because of the prevalence of these diseases in albino rats when their diet is also inadequate in this vitamin. Wilson and DuBois'[31] pathologic studies of a fatal case of nutritional keratomalacia in an infant 5 months of age revealed extensive keratinization of the bronchial epithelium in many places, bronchiectatic cavities and abscesses. There was also extensive peribronchitis and interstitial emphysema. In both the trachea and the larynx was some stratified squamous epithelium, in which there was a slight degree of cornification. Hume and Smith[32] and others feel that partial deficiency of vitamin A is not uncommon and that a condition of latent deficiency results, in which the individual is liable to infectious invasion of the mucous membranes, more particularly those of the respiratory passages. Herbert,[33] in India, mentioned changes in the mucous membrane of the mouth and larynx, causing hoarseness, nasal catarrh and bronchitis. The familiar chronic diarrhea and a characteristic rise in temperature, features which Pillat stressed, are also noted.

### THE ALIMENTARY TRACT

The extent to which the alimentary tract may be involved in vitamin A deficiency is at present conjectural, owing to the dearth of trustworthy clinical observations and material for histopathologic study. In Wilson and DuBois' case, no noteworthy abnormality was found in the stomach, pylorus, duodenum, ileum or colon. In the pancreas, however, there were marked changes. There were numerous epithelial-lined cystlike cavities, which apparently were dilated acini. There were also marked inflammatory and fibrotic processes throughout the gland. Various writers have recorded the frequency of diarrhea in both children and adults who were suffering from this form of avitaminosis. Pillat expressed the belief that such diarrhea has its origin in a simultaneous degenerative disease of the intestinal mucous membrane similar to the diarrhea accompanying severe mehlnährschäden, as noted in Germany and Austria. The high incidence of intestinal disease in monkeys subjected to a shortage of vitamin A, according to Tilden and Miller[34] and McCarrison, the atony, changes in haustral marking and increase in the length of the colon of man during periods of malnutrition, as reported by Graham and Fletcher,[35] and the frequent striking therapeutic effect of a high vitamin diet in the latter instance and in ulcerative colitis would argue for a causative relationship between intestinal dysfunction and disease and avitaminosis. To what extent a deficiency of vitamin A in man plays a primary or exclusive part remains to be determined, for lack of other vitamins, especially C and G, is known to cause pathologic changes in the gastro-intestinal mucous membrane. Fehr[36] has observed that keratomalacia develops with essential atrophy of the intestinal tract. McCarrison noted that gastric and duodenal ulcers were very common in southern India. He was able to reproduce very small gastric ulcers in two groups of albino rats on diets resembling in deficiency in vitamins A, B and C and in other respects that of two of the poorer classes of the population. In one group he also noted changes characteristic of duodenitis. To what extent vitamin A played a part, if any, again remains to be determined. The inability to produce actual duodenal ulcers in any of the experimental animals seems disconcerting, for 90 per cent of all peptic ulcers in man are duodenal. These results argue for conservatism in drawing conclusions, at least so far as the causal relationship between any particular phase of avitaminosis and duodenal ulcer is concerned.

On the other hand, disease of the liver or pancreas, when associated with impaired digestion and assimilation of fat, may provoke nutritional keratomalacia. Bloch has noted reports of such cases in the older literature. Blegvad recently has observed xerophthalmia in a case in which carcinoma of the liver occluded the common bile duct. Wright has noted a similar case. Pillat believes that severe infectious intestinal disease, such as typhoid and dysentery, may act as an exhaustive factor, and may lead, indirectly, to the outbreak of keratomalacia in adults, as it does in children.

### THE GENITO-URINARY TRACT

The strikingly high incidence of urinary calculi and deposits of calcium in the experimental animal deprived of an adequate supply of vitamin A may have its counterpart in man, but observations on the latter are conspicuous by their absence. Research bearing on the changes in the epithelial tissues of the reproductive organs of experimental animals of both sexes and on their deleterious influence on the function of reproduction, likewise, has not as yet been substantiated in man. Therefore no conclusions can be drawn at present concerning the formation of urinary calculi and the influence on reproduction in the human being. In Wilson and DuBois' case, keratinization of the epithelium of the renal pelvis was found. The uterine epithelium of the fundus was nearly replaced by stratified squamous epithelium, and where so replaced the uterine glands were absent. Bloch noted complicating pyelitis in eighty-six cases of keratomalacia in children. Herbert reported an increase of epithelial cells in the urine, and Spence[37] made similar observations in seventeen cases of nutritional xerophthalmia and night blindness. The possible part played by vitamin deficiency in its relation to puerperal sepsis will be considered presently.

### CUTANEOUS SYSTEM

Pigmentation of the conjunctiva in xerophthalmia and xerosis conjunctivae, apparently confined to the dark-skinned races, has been reported by Herbert, by Wright, and by Pillat and King.[38] Chou[39] stated that it is the earliest sign of xerophthalmia. As the condition of the conjunctiva improves, much of the pigment disappears, but some of it remains permanently. This pigmentation is the result of an increased amount of melanin normally present in the basal epithelium, and, according to Collins,[40] is also present in the more superficial, even in the keratinized, layers.

Bloch and others have called attention to the dry, scaly, shriveled condition of the skin among infants affected with this disease. Pillat maintained that, apart from the eye, the skin undergoes the most marked and extensive change of all. In this, the sebaceous and sweat glands, hair and nails participate. He, and Frazier and his associates,[41] detailed these various changes. The latter investigators characterized them as xerosis and hyperpigmentation, and in some, ulcerative lesions and pustulation developed. In the group reported by Frazier and his associates, mostly observed in adult Chinese soldiers, the cutaneous changes developed even before xerophthalmia was apparent, and there was no clinical evidence of beriberi, scurvy or pellagra. Curiously enough, the cutaneous lesions were essentially identical to those of the series of cases of scurvy described by Nocolaŭ,[42] Wilshire[43] and others. Frazier, however, attributed the cutaneous changes to vitamin A deficiency. Furunculosis, coming in the category of pustulation or pyodermia, one of the common sequelae of cutaneous changes in xerophthalmia, was noted by Bloch, Ross, Spence and others.

### HEMATOPOIETIC SYSTEM

Berglund, Keefer and Yang[44] described a form of secondary anemia which they considered to be associated with deficiency in the fat-soluble food factor. They made the reservation, however, that other factors seem to be necessary to bring the anemia into existence. In their series of cases, administration of cod liver oil caused a rise in the reticulocyte count of from 1 to 30 per cent. Other observations have been made by Keefer and Yang,[45] Pillat, and Pillat and Yang,[46] who have also stressed factors other than actual vitamin deficiency itself as the cause of the anemia so frequently observed. John[46a] did not find any change in the velocity of sedimentation of erythrocytes in this deficiency disease that was not due to other associated conditions. Sure, Kik and Walker[47] were unable to substantiate the observations of Koessler and his co-workers[48] that there is a relation between vitamin A deficiency and pernicious anemia.

### CENTRAL NERVOUS SYSTEM

Until recently, vitamin B and possibly G were the only vitamins held to play any important part in maintaining a healthy condition of the nerves. Nothing has been known clinically, up to the present time, of the involvement of the nerves in vitamin A deficiency.

The experimental researches of Mellanby[49] have shown that diets containing a large amount of cereals, and deficient in vitamin A or carotene, when fed to young puppies caused degeneration of the spinal cord in the form of demyelination of the nerve fibers. Moreover, it was definitely established experimentally that the effect of the neurotoxin of ergot and cereals is neutralized by this vitamin. These results have a possible bearing on convulsive ergotism, lathyrism, pellagra and the subacute, combined degeneration of pernicious anemia, tabes dorsalis and disseminated sclerosis. In a communication on pellagra, Eusterman and O'Leary[50] have shown that this disease, for various reasons, may be constantly in our presence and that it has a universal distribution. Therefore the part that vitamin A deficiency plays, as regards lesions of nerves, and the causative relationship of the toxic element in maize and cereal to pellagra might be determined by clinical investigation. John has noted that in vitamin A deficiency the patients are mentally numb and apathetic. Bloch has commented on the fact that children are indolent in the first stages and later extremely irritable. John's observations on the changes in corneal sensibility and the possible relationship of xerophthalmia to lesions of the central nervous system have already been considered.

### RELATION OF VITAMIN A DEFICIENCY TO INFECTIONS IN GENERAL

Many observers are agreed that vitamin A is a physiologic prophylactic against infection, by virtue of the fact that it maintains the integrity of the epithelial linings of the mucous tracts and the skin, but its "antiinfective" function, that is, its ability to cure infections when the barrier of the mucous membrane has been passed, or to prevent or cure infections of the blood stream, is still not established. The marked susceptibility to, and the high incidence of, infections in the experimental animal, as a rule rather extremely deprived of vitamin A, is the usual and early observation of all research workers. Accumulating experimental evidence, however, tends to support the hypothesis that vitamin A plays a part as an antiinfective agent. It seems logical that these observations can be translated into terms of human experience, the differences being mostly those of degree. It will be recalled that Bloch noted many severe infections in his eighty-six xerophthalmic patients. In addition to pneumonia and bronchitis in twenty-seven, there was otitis media in thirteen, pyelitis in twenty-seven and pyodermia in fourteen cases. He maintained that vitamin A is of especial importance to the organism for resisting and overcoming infections, and that this applies to vitamin A only. Spence's experience in seventeen cases of nutritional xerophthalmia and night blindness, chiefly in older children and young adolescents, stands in contrast to that of Bloch. There was a high incidence of cutaneous infection, impetigo and boils in the families (ninety-nine members) of the eleven youngest patients. In seven of the latter there was a history of indolent infection of the skin. This was promptly cured by antixerophthalmic treatment. But over a period of two years the only serious, febrile illnesses in these families, living on a xerophthalmia-producing diet, were a fatal case of pneumonia in a girl 14 years old, and two cases of mumps and three of measles, with complete recovery. A clinical study of the relationship of vitamin A to the "common cold" by Wright and his associates[51] failed to disclose any appreciable difference in the incidence of this infection in groups of children supplied with normal amounts of vitamin A and those supplied with large amounts of this vitamin. In the treatment of patients with pneumonia at the Crown Gold Mines in Johannesburg, Donaldson[52] found that in 200 cases in which large doses of vitamin A were given the mortality rate was 8 per cent, whereas in a control group of 100 cases the mortality rate was 13 per cent. To determine the particular part that vitamin A plays in the favorable therapeutic effect of high vitamin diets in such chronic infectious conditions as rheumatoid arthritis and pulmonary tuberculosis requires further investigation.

Mellanby and Green [53] reported success in the treatment of puerperal sepsis with vitamin A concentrates. These cases were not of the fulminating type and constituted too small a number from which to draw definite conclusions as to the antiinfective potency of this vitamin. The investigations of Burton and Balmain [54] and of Cramer [55] tended to discredit the hypothesis that vitamin A has an antiinfective effect, but the results of recent studies by Green, Pindar, Davis and Mellanby [56] are more convincing as to the part diet plays as a prophylactic agent against puerperal sepsis, and vitamin A as an antiinfective agent. Of 275 pregnant women who were given vitamin A concentrates and vitamin D during the later weeks of pregnancy, in only 1.1 per cent did morbidity according to the British Medical Association standard develop; among a similar number of pregnant women acting contemporaneously as controls there was a morbidity of 4.7 per cent. Further clinical investigations along these lines, particularly as they concern pyogenic infection of various organs and tissues, are desirable.

### TREATMENT OF VITAMIN A DEFICIENCY

The treatment of vitamin A deficiency states in the absence of intestinal and hepatic diseases, which prevent adequate absorption and metabolism of vitamin A, is as simple as the prevention of such a deficiency. Prevention should be the keynote in a consideration of the treatment of such conditions. Prevention or cure of the deficiency state itself is very readily accomplished by means of a diet containing adequate vitamin A. The foods rich in this vitamin, as previously mentioned, are butter, milk, cod liver oil, and vegetables containing green and yellow pigment. That the ordinary American dietary contains foods adequately supplied with this vitamin is attested by the rarity of such diseases in the United States. There is no evidence that the normal person fails to absorb vitamin A or its precursor, carotene.

Spence noted that from 10 to 15 cc. of cod liver oil daily was sufficient to cure xerosis in man almost as rapidly as in cases treated with large amounts of cod liver oil and butter. He noted improvement in night blindness in from three to five days after the onset of the treatment, and in from seven to fourteen days vision was apparently normal. Bitôt's spots became somewhat fragmented and decreased in size, and in the severest cases had completely cleared in five or six weeks. Two months was adequate time in which to clear up all signs of the disease. Liver extract, exposure to irradiation by the mercury vapor lamp daily for four weeks, and administration of irradiated ergosterol were without therapeutic effect on xerosis.

If disturbances of gastro-intestinal or hepatic function, or of absorption, are of such degree as to prevent oral administration of foods rich in vitamin A, the substance may be administered parenterally, with equal effectiveness. Bloch [57] noted the efficacy of subcutaneous injections of cod liver oil (sterilized by boiling) in vitamin A deficiency states; doses were of 0.5 cc., raised to 1 cc. daily, for from four to eight days. Blegvad [58] cited a method of producing a preparation with a potency 100 times that of cod liver oil, which may be used subcutaneously. He used this successfully in treatment of night blindness and xerosis due to faulty assimilation, in a case in which there was carcinoma of the liver and jaundice, after a diet high in vitamin A had been ineffective during a trial of six weeks. This patient was given 1 cc. subcutaneously every other day, with apparent rapid absorption and without local inflammation; after two injections the xerosis disappeared, and after six injections the patient could read in dim light. These observations are borne out experimentally by the work of Koehne and Mendel,[59] who showed that rats deficient in vitamin A unquestionably were able to utilize the vitamin A content of cod liver oil administered subcutaneously. There was little evidence, however, that the oil itself was utilized.

# THE PERCENTAGE OF OCCUPANCY IN AMERICAN HOSPITALS

C. RUFUS ROREM, Ph.D., C.P.A.
CHICAGO

The greatest economic problem before the hospitals of the United States today is the adequate utilization of the hospital facilities and personnel. To study this problem a special committee of the American Hospital Association was appointed by its president, Mr. Paul H. Fesler. The following facts, among others, were gathered for the purposes of the committee. These data are based solely on material accumulated by the Council on Medical Education and Hospitals of the American Medical Association.

### THE TRENDS IN HOSPITAL OCCUPANCY

In table 1 there are compared the total beds and the percentage of occupancy in hospitals registered by the American Medical Association, according to type of control, for five successive years, from 1927 to 1931. This table shows that the percentage of occupancy has remained almost constant for this entire period for both government and nongovernment hospitals, nearly 90 per cent for the former and something more than 60 per cent for the latter. There has been a consistent growth in the bed capacity of the government hospitals with an average increase of approximately 20,000 beds

Table 1.—*Bed Capacity and Percentage of Occupancy in Hospitals Registered by the American Medical Association, According to Type of Control, for Five Successive Years*

| | Control | | | |
|---|---|---|---|---|
| | Government | | Nongovernment | |
| Year | Bed Capacity | Percentage of Occupancy | Bed Capacity | Percentage of Occupancy |
| 1927 | 545,169 | 84 | 308,149 | 65 |
| 1928 | 567,434 | .... | 325,500 | .... |
| 1929 | 582,537 | 88 | 324,596 | 64 |
| 1930 | 619,726 | 89 | 336,143 | 63 |
| 1931 | 641,524 | 89 | 332,591 | 62 |

a year. In contrast, the years 1929 and 1931 show slight decreases in the total bed capacity in nongovernment institutions. The number of occupied beds in nongovernment institutions increased very slowly except in 1931, when the total was actually less than for the year 1930.

TABLE 2.—*Bed Capacity and Percentage of Occupancy in General and Nervous and Mental Hospitals Registered by the American Medical Association, for Five Successive Years*

| | Type of Service | | | |
|---|---|---|---|---|
| | General | | Nervous and Mental | |
| Year | Bed Capacity | Percentage of Occupancy | Bed Capacity | Percentage of Occupancy |
| 1927 | 345,364 | 66 | 373,364 | 93 |
| 1928 | 363,337 | .... | 394,364 | .... |
| 1929 | 357,034 | 65 | 414,386 | 95 |
| 1930 | 371,609 | 65 | 437,919 | 95 |
| 1931 | 384,333 | 65 | 451,245 | 95 |

In table 2 there is set forth a comparison of the total and occupied beds in general and in nervous and mental hospitals registered by the American Medical Association for the five-year period 1927-1931. There has been a steady increase in the bed capacity of the nervous and mental hospitals during this entire period, with a much slower and a much less regular increase in the bed capacity of the general hospitals.

The nervous and mental hospitals have been occupied to approximately 95 per cent capacity during this five-year interval, whereas the occupancy of general hospitals has been approximately 65 per cent. The reduction in reported bed capacity for general hospitals in 1929 was in part the result of a reclassification of hospitals on the part of the American Medical Association. The facilities of some hospitals were removed from the register or classified as "institutional" rather than as "general" hospital beds.

### THE VARIATIONS AMONG "GENERAL" HOSPITALS

Table 3 represents the proportions of occupied beds in 3,952 general hospitals registered by the American Medical Association in 1930 according to the bed capacity of the hospitals. The percentage of occupancy increases with the average size of the institution. For the small hospitals (fifty beds or less) the average occupancy is approximately 50 per cent. This proportion increases to 59 per cent for hospitals with from 51 to 100 beds each and reaches an average of about 65 per cent for the hospitals ranging from 101 to 300 beds per institution. The proportion of occupancy for the two larger groups are 72 per cent and 80 per cent, respectively.

TABLE 3.—*Number, Total Capacity and Percentage of Occupancy of Registered General Hospitals in the United States, 1930, Classified According to Size of Hospital (Excluding Hospitals Registered as "Related Institutions")*

| Size of Hospital | No. of Hospitals | No. of Beds | Percentage of Occupancy |
|---|---|---|---|
| 10- 50 | 2,141 | 58,559 | 49 |
| 51-100 | 844 | 63,069 | 59 |
| 101-300 | 790 | 136,577 | 65 |
| 301-500 | 105 | 39,989 | 72 |
| Over 500 | 72 | 71,721 | 80 |
| Total | 3,952 | 369,915 | 65 |

A partial explanation of the higher percentage of occupancy in the large institutions is the fact that most of them are under government auspices. The lower percentage of occupancy in small hospitals is not as serious a condition as would at first appear. Many of these small hospitals are primarily adjuncts to the private practice of independent physicians, containing apparatus and equipment to round out the physician's office practice. Some of these small institutions are the only hospitals in the town or community and as such must be regarded as emergency stations whose primary function is readiness to serve a community when a severe illness or accident occurs. The burden to maintain these hospitals ready to serve the community, therefore, is primarily one for the community as a whole to bear, and the low degree of utilization of bed capacity is not as serious as if there were several institutions standing side by side each with low percentages of occupancy.

An analysis was also made of occupied and unoccupied beds in these 3,952 general hospitals in 1930 classified according to type of control, as shown in table 3. The average occupancy of these government hospitals for acute diseases and conditions in 1930 was 75 per cent, whereas only 62 per cent of the beds in nongovernmental general hospitals were occupied daily.

TABLE 4.—*Number, Total Capacity and Percentage of Occupancy of Registered General Hospitals in the United States, 1930, Classified According to Type of Control (Excluding Hospitals Registered as "Related Institutions")*

| Type of Control | No. of Hospitals | No. of Beds | Percentage of Occupancy |
|---|---|---|---|
| Governmental: | | | |
| City and county | 441 | 68,753 | 75 |
| State | 46 | 14,039 | 83 |
| Federal | 201 | 32,368 | 70 |
| Total governmental | 688 | 115,160 | 75 |
| Nongovernmental: | | | |
| Church and fraternal | 851 | 105,371 | 63 |
| Industrial, individual and partnership | 964 | 24,745 | 49 |
| Independent | 1,449 | 124,639 | 62 |
| Total nongovernmental | 3,264 | 254,755 | 62 |
| Total | 3,952 | 369,915 | 66 |

The city and county hospitals represent the largest number of beds for acute diseases and conditions under governmental auspices. These institutions maintained during 1930 a 75 per cent capacity. A higher percentage prevailed for the state institutions, although they contain a smaller number of beds for acute diseases and conditions.

The church and fraternal hospitals show approximately 63 per cent occupancy; the industrial and independent and partnership hospitals, 49 per cent, and the independent institutions, 62 per cent. Many of the "independent" hospitals are organized as private corporations for profit. It is this group of institutions which has particularly suffered through reduction in occupancy during recent years.

### CONCLUSION AND SUMMARY

Are the American hospitals actually serving the public to the greatest advantage? The answer to the question lies in part in the extent to which the facilities are utilized at any given time or during a period of time. The degree of utilization may be expressed in terms of the amount of service rendered and may apply not only to "beds" but also to the professional personnel and scientific apparatus and equipment. The foregoing paragraphs have dealt solely with the facilities of the hospital so far as they can be expressed in terms of numbers of beds. It is recognized, of course, that the bed capacity of a hospital is merely one expression of its available scientific facilities. In addition, there are important capital investments in other scientific apparatus, such as laboratories, the x-ray department, the outpatient service, and physical therapy. It is quite possible that in a particular institution these scientific items of equipment would be used to a high degree of capacity, even though the beds of the institution were not filled with patients. This will be particularly true in a hospital that maintains a large outpatient service or in a private hospital owned and conducted by a clinic that utilizes the scientific apparatus and equipment for the office practice of the physician members of the group.

The data set forth in these tables indicate clearly that at the present time the beds in the general hospitals of the United States are able to take care of an increased number of persons during any particular year and at any particular time. Whether or not these proportions are too large or too small cannot be answered for the country as a whole, for in some communities there is still need of additional institutions, while other communities admittedly have more facilities than can be properly used.

Julius Rosenwald Fund.

# *Council on Pharmacy and Chemistry*

## NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

SUPRARENIN (See New and Nonofficial Remedies, 1932, p. 187).

The following dosage forms have been accepted:

*Suprarenin Solution, 1:1,000:* Each 1 cc. contains suprarenin bitartrate equivalent to suprarenin 0.001 Gm. (1/65 grain).

*Ampules Suprarenin Solution:* Each 1 cc. contains suprarenin bitartrate equivalent to suprarenin 0.001 Gm. (1/65 grain).

## REPORTS OF THE COUNCIL

The Council has authorized publication of the following report.

W. A. Puckner, Secretary.

### ANTIOPIN NOT ACCEPTABLE FOR N. N. R.

Antiopin, marketed in the form of tablets, is claimed to be "an efficacious remedy for morphine and cocaine poisoning," it being stated that after administration to an addict for ten to fourteen days morphine can be totally dispensed with; also that the preparation is efficacious in cases of cocaine poisoning, and that alcoholism and nicotine poisoning can be cured with it. The Council took up the consideration of this preparation at the request of Walter Grautoff, New York, who transmitted information concerning the product which was supplied by the manufacturer, Dr. K. Yamada's Chemical Laboratory, Kobe, Japan.

Antiopin is claimed to be a mixture of "Euphrasin" 5 per cent, quinine hydrochloride 10 per cent, caffeine 15 per cent, lactose 40 per cent, sucrose 20 per cent, acacia 10 per cent. The "Euphrasin" component is stated to consist of "extract from 'Kofuku' Sea-ear" 10 Gm., quinine hydrochloride 9.5 Gm., urea 1 Gm. "to which hydrochloric acid and alcohol are added, and the mixture is heated and condensed. It is then allowed to absorb in 20 grammes of lactose, left to dry and then made into powder." While the statement in regard to the preparation of the mixture designated "Euphrasin" is not clear and while the weight of the tablets is not declared, it is evident that Antiopin is claimed to contain small quantities of an extract prepared from the entrails of a certain kind of "ear shell," in admixture with quinine hydrochloride, caffeine and urea. The details of the method of preparation of the extract from the entrails of "'Kofuku' ear shell" are not furnished nor is any information made available in regard to the chemical composition of this extract or its pharmacologic properties.

The name Antiopin is not descriptive of the composition but, instead, is evidently intended to indicate its use in the treatment of opium poisoning.

In the circular that accompanies the trade package, Antiopin is "recommended to those, who desire to radically get rid of the habitual use of morphine or opium . . ." and also "to those who do not wish to discontinue the habit but are afraid of the poisonous effects." It is further claimed that Antiopin "is efficacious for strengthening the digestive organs, building up the strength and mitigating or stopping pain" and that it is "especially recommended in the case of stomachache, gripe or diarrhoea."

No evidence is offered for the effectiveness of Antiopin in the treatment of alcoholism, nicotine poisoning, "stomachache, gripe or diarrhoea." As evidence for the efficacy of the product in the treatment of drug addiction, the Council was supplied with translations of reports of trials carried out in Japan. The reports lack all control and do not constitute acceptable evidence. Seldom has a preparation been presented for consideration with such extraordinary claims, with so little evidence concerning the nature of the substance used, without the least pharmacologic study of its actions, and with so little evidence of its therapeutic value. Naturally, it is impossible for one to say what an extract of the intestine of the Japanese fish the "kofuku," or earshell, contains, and there is no excuse for offering the physician a preparation with such extraordinary claims without the slightest information concerning the pretended active constituent of the preparation.

There are few more tragic chapters in medicine than that relating to morphine addiction and its treatment. Without referring further to the innumerable fraudulent "cures," which usually consist of mixtures of morphine, many methods have been put forward in good faith and employed following enthusiastic reports of their successful use, only to fall into oblivion because they were incapable of modifying the course of withdrawal appreciably. The following quotations from two papers illustrate the difficulty of evaluating substances used in the treatment of morphine addiction, even by recognized specialists: "Some 219 men and 147 women have been given this treatment. It has shown itself to be of unquestioned value, producing a successful withdrawal of the drug in a few days, in some instances with but little discomfort, and *in all instances with less suffering than the ordinary withdrawal method.* [Italicized by the editor.] The patients sleep without hypnotics of any kind during and after their treatment, and at the end of a few days are hungry, and digest easily all that their renewed and voracious appetites cause them to take" Lambert, Alexander, and Tilney, Frederick: The Treatment of Narcotic Addiction by Narcosan, *M. J. & Rec.* **124**:764 [Dec. 15] 1926). "The Narcosan treatment was given to sixty-eight patients.— The results were clear cut. In the Narcosan-treated group there were noted a greater occurrence and intensity of all the symptoms mentioned. Taking an average of the sixty-eight Narcosan-treated cases, there was found in the former a more marked restlessness and muscular twitching, and particularly a greater intensity in the gastro-intestinal symptoms, vomiting, diarrhea and cramps, and in general prostration. In short, the symptoms occurring in patients receiving Narcosan were more severe than in those not receiving Narcosan. Further, in regard to recuperation after the withdrawal period, the Narcosan-treated patients did not show any advantage over the controls" (Lambert, Alexander, and others: Narcosan for Drug Addiction, Report of the Mayor's Committee of New York on Drug Addiction, J. A. M. A. **92**:147 [Jan. 12] 1929).

The Council declared Antiopin unacceptable for New and Nonofficial Remedies because the preparation is a mixture of indefinite composition, offered under a nondescriptive, therapeutically suggestive name and marketed in a way that may foster the drug habit.

# HOSPITAL SERVICE IN THE UNITED STATES

## ELEVENTH ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Fourteen to a minute is the rate at which the hospitals of the United States are admitting patients. For twenty-two years, hospitals have been built and equipped at the rate of one sixty-nine bed hospital each day, including Sundays and holidays. This means that hospitals have increased about 25,000 beds annually during that time. The number of physicians connected with hospitals is 116,363. The number of patients admitted in 1931 was 7,155,976. Hospitals were the birthplaces of 708,889 babies during the last fiscal year, and the number of hospital births is increasing at a rate of around 50,000 a year.

One or more hospitals are located in each of 1,875 counties, or 70 per cent of the total 3,074 counties in the United States. In 1920 only 1,332, or 44 per cent of the 3,027 counties then laid out, had any kind of hospital. In the past twelve years, therefore, one or more hospitals have been built in 543 counties which previously did not have a hospital within their borders.

The total patients admitted during any year has just been ascertained for the first time since 1872, through the Annual Census of Hospitals for 1931 by the Council on Medical Education and Hospitals, a report of which is herewith presented.

The care of the sick and injured in the United States requires 6,613 hospitals with a total capacity of 974,115 hospital beds. Twenty-two years ago, fewer than half that number of hospital beds were in existence. Hospital service as it existed in the United States sixty years ago is described in a twenty-five page report printed in the Transactions of the American Medical Association for 1873, volume 24. That report contains the names of 178 hospitals having a total capacity of 35,604 beds, to which were admitted 146,472 patients during the year 1872. There were 309 resident medical officers in addition to 580 members of attending medical and surgical staffs. Forty medical students were employed. The greatest number of hospitals in any one state was 53 in New York, followed by 22 in Pennsylvania, 17 in Illinois and 13 in Massachusetts. According to that early report, 18 of the 178 hospitals had a capacity of 400 beds, 38 hospitals between 200 and 400, 46 between 100 and 200, and 14 between 40 and 100; 22 had a capacity of 50 beds or less. The sum total of patients admitted was only 146,472. Only 9 hospitals reported that they were connected with medical colleges. However, an additional 36 stated that clinical instruction was given in their institutions. Thirty hospitals were supported by states, 15 by cities, 4 by counties, 7 by religious denominations and 67 by "patients and other sources." That early report was compiled from a survey conducted by the United States Bureau of Education and its publication in the Transactions was arranged by J. M. Toner, M.D. Just why no authentic figures on hospital service were available between 1873 and 1909 is not easily explained. The next actual census of hospitals worthy of recognition for completeness, after the one of 1873, was that contained in the second edition of the American Medical Directory in 1909. Each succeeding edition has given a list of hospitals existing at the time. In recent years, more accurate and more complete data have been obtained through the annual census of hospitals.

### AMERICAN SYSTEM OF HOSPITALS

The American people have developed a system of hospital service in their own way. Realizing that the care of the sick is always the duty of the well, they have performed that duty in every community, using whatever agency or organization seemed best adapted or most available for the operation of hospitals. Hospitals are maintained by a number of agencies both governmental, such as federal, state, county and city governments, and nongovernmental, such as churches, fraternities, industries, individuals and incorporated associations.

The government owned hospitals now number 1,816, with a total capacity of 641,524 beds and an average daily census of 569,301 patients. All hospitals other than the government owned had an average daily census of 206,095. On the other hand, the total patients admitted by all government owned institutions was only 1,833,078, as compared with 5,322,898 patients admitted to all nongovernment institutions during the last fiscal year. These figures, of course, reflect the preponderance of custodial care in the government supported institutions. It would be a mistake, however, to conclude that governmental agencies are not interesting themselves in the care of other than custodial cases, because acute medical and surgical care is maintained for the patients and inmates of some federal and state institutions that are primarily designed for custodial care. Reference to accompanying compilations will support these deductions, and the columns of figures arranged by states are bristling with interesting facts. There is a tendency for the federal government to extend constantly hospital care to veterans for nonservice connected disabilities. The report of the Veterans' Administration for 1931 (p. 62), shows that of 102,226 admissions of World War veterans in that year, 75,427, or 73.8 per cent, were for non-service connected disabilities.

### FEDERAL HOSPITALS

Reports were received from 291 hospitals and related institutions owned and operated by the federal government. Those institutions have a total capacity of 69,170 beds and 391 bassinets. The total number of patients admitted was 301,149. The total average daily census of patients in federal hospitals was 52,881. The hospital work now being carried on by the various branches of the federal government is as follows:

| | Hospitals | Beds | Bassinets |
|---|---|---|---|
| Veterans' Administration Hospitals | 55 | 28,454 | ... |
| Veterans' Administration Homes | 10 | 6,537 | ... |
| Army | 95 | 10,789 | 155 |
| Navy | 16 | 8,735 | ... |
| U. S. Public Health Service | 26 | 4,763 | ... |
| Indian Service | 80 | 3,833 | 210 |
| All other federal hospitals | 9 | 6,059 | 26 |
| Totals | 291 | 69,170 | 391 |

Taken in order of bed capacity, the Veterans' institutions come first, followed in order by the Army, Navy, United States Public Health Service and United States Indian Service.

The data received from the Veterans' Administration as well as that received from individual institutions indicate two types of service: the Veterans' Administration Hospitals and the Veterans' Administration Homes, formerly called National Homes for Disabled Volunteer Soldiers. The veterans' hospitals number 55, with a total capacity of 28,454. In the ten Veterans' Administration Homes there were 6,537 beds. The annual report of the Administrator of Veterans' Affairs for the year 1931 (p. 15) says:

> Of the total of 109,649 admissions of veterans during this year 58,894, or 54 per cent, were made to hospital facilities under the control of the Veterans' Administration; 25,490, or 23 per cent, to naval hospitals; 12,093, or 11 per cent, to Army hospitals; 7,966, or 7 per cent, to Marine hospitals, and 5,206, or 5 per cent, to state and civil institutions and to hospitals in Washington, D. C., operated by the Interior Department. It is significant to mention that during this fiscal year only 4.7 per cent of the total admissions were made to civil and state institutions, while in 1920 and 1924 these figures were approximately 45 per cent and 19 per cent, respectively.

In contrast with the comparatively even distribution of all types of civilian hospitals, the fifty-five Veterans' Administration hospitals are located in New York, four; California, Illinois, Massachusetts, Missouri and Pennsylvania, three each; Arizona, Georgia, Indiana, Kentucky, Minnesota and Washington, two each. The remaining states have one hospital each except Delaware, Kansas, Maine, Nevada, New Hampshire, Rhode Island, South Carolina, South Dakota, Utah, Vermont, Virginia, West Virginia and Wisconsin, in which no veterans' hospitals are reported. The ten Veterans' Administration homes are located one each in California, Illinois, Kansas, Maine, New York, Ohio, South Dakota, Tennessee, Virginia and Wisconsin.

It would seem, therefore that the distribution of veterans' hospitals is not adapted to the care of veterans in the case of acute illnesses and accidents.

The Army exceeds all other branches of the federal hospital system as to the number of hospitals, there being ninety-five Army hospitals with a bed capacity of 10,789.

The sixteen hospitals under the Navy Department have a capacity of 8,735 beds.

The United States Public Health Service, conducting the Marine Hospitals and others, accounts for twenty-six hospitals, with a capacity of 4,763 beds. The United States Indian Service maintains eighty hospitals. The total bed capacity of the Indian hospitals, however, is only 3,833.

All other federal hospitals not accounted for in the foregoing consist of the St. Elizabeths Hospital (two units), the Freedmen's and the Hospital of the National Training School for Boys, at Washington, D. C.; three United States Penitentiary Hospitals; the Morningside Hospital at Portland, Ore., and the W. B. Lewis Hospital in the Yosemite National Park.

The Army hospitals have 155 bassinets and reported 1,387 births for the year. In the Indian Service there were 210 bassinets, and 1,188 births were reported. In other federal hospitals there were 421 births, making a total of 2,996 babies born in the federal institutions.

The decrease in the number of federal hospitals in the past five years, shown by table 1, is due to the dropping of a number of small institutions, mainly army post hospitals, from the register of hospitals. In the same five years the capacity of federal hospitals has increased from 60,444 beds to 69,170 beds, and the average number of patients has increased from 42,137 to 52,881.

### STATE HOSPITALS

State hospitals likewise have decreased in number, but their capacity has grown in the last five years from 354,786 beds to 419,282 beds. The average number of patients in state hospitals has mounted from 328,737 to 394,938 in five years. State hospitals reported that they admitted 388,984 patients during the last fiscal year.

For a proper understanding of the facts brought out in table 1, it is necessary to bear in mind that the nongovernmental agencies mainly, though not entirely, run hospitals for the care of acutely sick and injured, while the governmental institutions were designed mainly, but not entirely, for the chronic cases. The care of persons who are disabled for a great length of time, frequently for a lifetime, is a distinct burden which the family and friends of the individual may be unable to assume. This is the fundamental reason why the custodial patients must be placed in tax supported institutions, while those who are only temporarily ill and those who are able to pay their own expenses can be cared for in hospitals maintained by agencies not dependent on taxation.

### COUNTY HOSPITALS

County hospitals have grown in number during the half decade from 480 to 508. This is a considerable net increase when it is considered that during the same time a great many small county institutions have been discontinued and their sick and injured transferred to larger county hospitals. The average daily census of patients in county hospitals has increased in the five year period from 47,704 to 62,862. The increase should be noted in the patronage of county hospitals since 1929, when they had an average daily census of 52,994 patients.

### CITY HOSPITALS

That city hospitals, as a group, are used more than other governmental hospitals for the care of the acutely sick and injured is evidenced by the fact that they admitted 689,259 patients during the last fiscal year, although their bed capacity was 61,351, which is considerably less than that of the county hospitals. The patronage of city hospitals, as indicated by the average daily census of patients, has dropped slightly in the past year; but they are still caring for considerably more patients than in 1929. The total births in city hospitals during the past two years increased from 45,787 to 58,311.

### CITY-COUNTY HOSPITALS

The operation of hospitals by the cooperation of city and county governments is of course purely a matter of local convenience. City-county institutions in the past five years have increased from 70 to 77. They admitted 108,450 patients last year and had an average of 11,766 patients. Births in the past two years increased from 8,806 to 10,660.

### CHURCH HOSPITALS

The 1931 census of hospitals gives churches the credit for 1,011 hospitals with a total bed capacity of 116,935, and with an average daily census of 73,911 patients. This average is a little lower than in 1929, when it reached a peak of 75,770, but the total number of patients admitted by this group of hospitals, 2,013,352, is greater than for any other nongovernmental group except independent hospital associations, which admitted 2,714,406 patients. The church hospitals have credit for 235,229 births, showing a healthy increase over 209,726 births in the same institutions two years ago. Church hospitals, being supported in a rather large part by donations, and the rest of their support coming mainly from patients, are among the hospitals that are most keenly feeling the effects of the depression. This is probably due to their inability to make collections from their pay patients rather than to any actual drop in patronage, for the average number of patients, 73,911, is only slightly below their peak of 75,770 for 1929. The average length of stay in church hospitals is thirteen days, one day shorter than in any other group.

### FRATERNAL HOSPITALS

Fraternal orders maintain 76 hospitals. The relatively small share of this group in hospital work is

reflected in the number of patients admitted, 44,790, the smallest number admitted by any of the groups contained in the report. The number of fraternal hospitals has declined from 85 five years ago. The capacity, at the same time, has increased from 4,935 to 5,528, and the average daily census of patients has increased from 3,193 to 3,820. The average length of stay per patient is thirty-one days; the births for 1931 numbered 2,054.

### INDUSTRIAL OR EMPLOYERS' HOSPITALS

Industrial hospitals have made a sharp decline in number from 161 to 135 during the past five years. Rather less is the decline in the number of beds, from 6,703 to 6,437 during the last year. The number of patients, at the same time, dwindled from 3,558 to 3,102. The comparatively large number of patients admitted, 91,166, of course reflects the short average stay of patients in industrial hospitals.

### INDIVIDUAL AND PARTNERSHIP HOSPITALS

The classification of individual and partnership hospitals shows evidence of a more rapid decline than any other group. There is, to be sure, still a comparatively large number, 1,560, of hospitals operated by individuals either singly or in partnership, the capacity of which has shrunk from 39,118 five years ago to 36,764 at the present time. In the same half decade the average number of patients dropped from 21,779 to 17,912. Only in the number of births have these proprietary institutions shown any considerable increase. They reported 39,436 births in 1929 and 42,268 in 1931.

### INDEPENDENT HOSPITAL ASSOCIATIONS

This group of hospitals represent a large and increasing number of associations usually formed for the express purpose of operating a single hospital in a given community. Some of these 2,015 organizations are incorporated for profit. The entire group admitted 2,714,406 patients in 1931, whose average length of stay in the hospital was fourteen days. They have a capacity of 166,927 beds, and their average daily census of patients is 107,350, only slightly below the corresponding figure for 1930. The number of births increased during the past two years from 283,136 to 318,251. This increase is explained, at least in part, by the general increased use of hospitals for maternity cases; also it is further explained by the fact that most of the hospitals maintained by independent hospital associations are general hospitals, nearly all of which have maternity services.

### HOSPITALS ACCORDING TO TYPE OF SERVICE

The differentiation and classification of hospitals according to type of service has been a natural development. There are, for example, the general hospital, the hospital for nervous and mental patients, for those suffering from tuberculosis, and various other types. The general hospital naturally constitutes by far the largest group.

*Total Patient Days and Average Length of Stay in Hospitals According to Control*

### GENERAL HOSPITALS

In communities that are only large enough to support one hospital, and this is true of the majority of communities in the United States, that hospital will be general. General hospitals have about held their own in number, since there were 4,322 in 1927 and 4,309 in 1931. But they have increased steadily in number of beds. The total bed capacity is 384,333, the largest capacity ever shown by this group. There are, in addition, 45,434 bassinets. The general hospitals last year admitted 6,321,861 patients, about 88 per cent of all patients admitted to all hospitals during the year. Another evidence of the importance of general hospitals is the fact that in them there were 641,823 births, out of a total of 708,889 births in all hospitals. The general hospitals, therefore, conduct 90 per cent of all the maternity service in all hospitals—in fact, they take care of more than ten times as many births as the maternity hospitals themselves. The average number of patients in general hospitals has shown a constant and rather decided increase in each annual census, being 247,560 for the year 1931.

*Total Patient Days and Average Length of Stay in Hospitals According to Types of Service*

| | 1929 | 1930 | 1931 | Average Length of Stay (Days) |
|---|---|---|---|---|
| General | 85,413,285 | 87,740,160 | 90,359,400 | 14 |
| Nervous and mental | 144,323,555 | 151,490,330 | 155,904,275 | 1,593 |
| Tuberculosis | 18,508,055 | 20,575,780 | 20,472,120 | 254 |
| Maternity | 1,245,380 | 1,505,990 | 1,729,005 | 19 |
| Industrial | 1,395,760 | 1,330,790 | 1,138,070 | 12 |
| Convalescent and rest | 1,674,620 | 1,837,410 | 1,616,585 | 57 |
| Isolation | 977,105 | 908,850 | 1,035,505 | 26 |
| Chil | 1,308,890 | 1,370,940 | 1,395,395 | 17 |
| | 460,995 | 523,045 | 527,060 | 5 |
| | 1,740,320 | 1,934,865 | 1,872,815 | 50 |
| Hospital departments of institutions | 5,688,160 | 6,517,075 | 5,930,885 | 45 |
| All other hospitals | 2,533,465 | 2,899,195 | 1,038,425 | 29 |
| Totals | 265,269,590 | 278,634,430 | 283,019,540 | 40 |

The rate of occupancy in general hospitals was 64.4 in 1931 as compared with 65.5 for the year 1929. It is in the general hospitals that the majority of interns receive their fifth year in medicine; here, also, the majority of the schools of nursing are conducted. The term "general" is usually understood to include the care of all kinds of sickness and injuries with the exception of mental conditions, contagious diseases and tuberculosis. Those types of cases, however, will occasionally be included among the patients of all general hospitals—in fact, the present survey shows that 313 general hospitals have wards, buildings or departments set aside for mental patients. It is not unusual for a general hospital to have a tuberculosis ward, building or department; and a place for the isolation of contagious or infectious cases is a necessity generally provided for.

### HOSPITALS FOR NERVOUS AND MENTAL PATIENTS

Hospitals for nervous and mental patients have continued to increase in number during the last year, but data on this point must be interpreted with care. While the Register of Hospitals lists 587 such institutions this year, as against 561 last year, some of the additions to this list represent changes in classification made possible by more complete information rather than the building of new institutions.

| All other hospitals | 2,364 | 2,197 | 1,262 |
| Total unoccupied beds, all hospitals | 180,367 | 192,487 | 198,719 |

The bed capacity in this group of hospitals has experienced a more definite increase, the figures growing from 437,919 in 1930 to 451,245 in 1931. The number of patients during the same period has grov from 415,042 to 427,135. These figures recall the co ditional statement made in the Hospital Number THE JOURNAL two years ago to the effect that thei would be a half million patients in mental hospitals i the United States by 1934.

The Council has this year, for the first time, collected data regarding the number of admissions to hospitals. According to reports received, the first admissions to nervous and mental hospitals for the year numbered 97,889. Complete data regarding discharges are not available.

The increase in bed capacity and patient population of mental hospitals has taken place almost entirely in federal and state institutions. This would naturally be true in a year of economic depression, and it is more true of mental hospitals than of others, because here the custodial aspect of hospital care is more dominant.

In this connection the average period of a patient's hospitalization is interesting. In mental hospitals last year it was 1,593 days. In tuberculosis hospitals it was 254 days. In general hospitals it was 14 days. Such figures raise questions as to how long a patient ought to be hospitalized and what criteria should determine the length of his stay; and if a patient remains for a longer period, the question arises whether the care given him is primarily custodial or therapeutic. If a hospital bed is occupied by the same patient for five successive years, is it a hospital bed and is he a patient? While other mental patients may be truly ill and receiving hospital care, this particular patient may be disabled rather than ill and his bed may have no rightful place in hospital statistics. In any case, the data given regarding mental hospital capacities and patient populations must be interpreted with care before comparisons are made with other groups of hospitals in which custodial care is quite exceptional and therapy the primary reason for every day's hospitalization.

*Percentage of Beds Occupied in Hospitals According to Types of Service*

| | 1929 | 1930 | 1931 |
|---|---|---|---|
| General | 65.5 | 64.7 | 64.4 |
| Nervous and mental | 95.7 | 94.8 | 94.6 |
| Tuberculosis | 82.7 | 85.5 | 85.0 |
| Maternity | 62.8 | 63.2 | 58.6 |
| Industrial | 54.6 | 53.0 | 48.1 |
| Convalescent and rest | 70.9 | 68.3 | 72.3 |
| Isolation | 36.1 | 32.7 | 38.6 |
| Children's | 65.9 | 67.0 | 69.9 |
| Eye, ear, nose and throat | 47.7 | 53.0 | 52.0 |
| Orthopedic | 80.2 | 83.5 | 78.1 |
| Hospital departments of institutions | 63.0 | 65.5 | 63.9 |
| All other hospitals | 74.6 | 78.3 | 69.2 |
| Total hospitals | 80.1 | 79.8 | 79.6 |

Increased attention has been called to the mental hospital group this year by a survey now being conducted by the Council on Medical Education and Hospitals, and already nearing completion. Thus far two steps have been taken in this investigation. Questionnaires have been mailed to all mental hospitals, and personal visits have been made to nearly all of them. The responses from these hospitals have been unusually hearty and, as a result, a great body of information never before in the Council's possession is now being organized and prepared for publication.

The treatment of mental patients has by no means been confined to mental hospitals. Three hundred and thirteen general hospitals report that they have separate departments for mental patients. These departments have a combined capacity of 12,066, and last year their total admissions were 78,122. A larger number of mental patients are being treated in outpatient departments of mental hospitals and in mental hygiene clinics. Many of these were formerly patients in mental hospitals and are still carried on parole.

### TUBERCULOSIS HOSPITALS

Whether or not patients suffering from tuberculosis should be admitted to general hospitals has been a question under discussion, and it is generally believed that such patients can be handled in general hospitals safely and often to the convenience and economic advantage of the community. Just the extent to which general hospitals have instituted tuberculosis departments is not known. It is known, however, that special hospitals for tuberculosis number 509, with a bed capacity of 65,923. They admitted 80,562 patients last year, and the average daily census of patients in those hospitals was 56,088. Tuberculosis hospitals remain practically stationary in number but have increased in bed capacity since 1927 from 63,170 to 65,923. The average daily census of patients in those hospitals has increased in the same time from 50,784 to 56,088.

### MATERNITY HOSPITALS

Maternity hospitals number 145, showing a constant decrease in number from 178 five years ago. They admitted 91,496 patients, and the average daily census of patients in those hospitals was 4,737. The total births numbered 61,363. Maternity hospitals, although becoming fewer in number, show a decided increase in bed capacity as well as in the number of bassinets and the number of births.

### INDUSTRIAL HOSPITALS

As the result, no doubt, of the depression, industrial hospitals have decreased during the past year from a capacity of 6,875 beds to 6,476 beds. The number of bassinets has dropped from 474 to 438, and the average daily census of patients from 3,646 to 3,118. It is only in the number of births in industrial hospitals, 4,543, that this type of institution has held its ground. The apparent slump here is due not only to the business depression but also, doubtless, to the fact that some industries which heretofore have hospitalized their own patients are now making use of other hospitals in the communities.

### CONVALESCENT AND REST HOSPITALS

In no other type of institution is there indicated a more decided decrease during the past year than in the institutions for convalescence and rest. First, there is a decrease in number from 162 to 133 and in bed capacity from 7,374 to 6,123, while the average daily census of patients dropped from 5,034 to 4,429.

*Percentage of Beds Occupied in Hospitals According to Ownership or Control*

| | 1929 | 1930 | 1931 |
|---|---|---|---|
| Federal | 76.8 | 79.2 | 76.5 |
| State | 94.6 | 93.8 | 94.2 |
| County | 80.7 | 82.2 | 81.2 |
| City | 74.3 | 75.9 | 76.3 |
| City-county | 80.2 | 81.6 | 82.0 |
| Governmental | 88.9 | 88.8 | 88.7 |
| Church | 66.7 | 64.2 | 63.2 |
| Fraternal | 68.7 | 67.4 | 69 0 |
| | 54.4 | 53.1 | 48.2 |
| | 54.2 | 51.7 | 48.7 |
| | 65.9 | 65.4 | 64.3 |
| Nongovernmental | 64.6 | 63.2 | 61.9 |
| All hospitals | 80.1 | 79.8 | 79.6 |

### ISOLATION HOSPITALS

The census shows that there are 86 isolation hospitals which admitted 40,210 patients during the last year, the average number of patients being 2,837. There is little change in the number and capacity of this type of institution, except an increase of about 400 for the year in the average daily census of patients. But if the statistics on isolation hospitals are taken for a five year period, there has been a decrease of 12 hospitals and of 1,200 beds. Part of this general decrease may be due to the increased use of general hospitals for certain types of contagious diseases.

### CHILDREN'S HOSPITALS

The 60 existing children's hospitals with their 5,463 beds and 273 bassinets admitted 83,416 patients last year; the average daily census of patients was 3,823.

Evidently the practice of pediatrics is carried on to a much larger extent in the pediatric departments of general hospitals than in children's hospitals. The amount of work handled by children's hospitals seems to about keep pace with the increase in population. It is not unusual to find the care of children combined, in small institutions, with a maternity service, and in some instances with orthopedics or throat, nose and ear services.

*Increase in Eight Years According to Ownership or Control*

| Control | Hospitals 1923 | Hospitals 1931 | Bed Capacity 1923 | Bed Capacity 1931 | Aver. Patients 1923 | Aver. Patients 1931 |

| Grand total, all hospitals | 6,830 | 6,613 | 755,722 | 974,115 | 553,133 | 775,396 |

EYE, EAR, NOSE AND THROAT HOSPITALS

The census of hospitals from year to year indicates a decline in this classification until, at the present, there are only 64 in the Register with a total bed capacity of 2,774 and an average daily census of 1,444 patients. There were 113,762 patients admitted. The majority of these hospitals are maintained by, or for, individual practitioners. The average length of stay per patient is five days.

ORTHOPEDIC HOSPITALS

The growth of orthopedic hospitals, which now number 68 with a total bed capacity of 6,569, seems to offer some justification for maintenance as specialized institutions. Figures are not obtainable by which the work of these institutions could be compared with that of the orthopedic departments of general hospitals. Reference to table 2 will enable the reader to trace the advance in the number and capacity of orthopedic hospitals. They admitted 37,842 patients during the last fiscal year.

*Summary of Growth of Hospitals, 1909 to 1931*

| | Federal Hospitals | | State Hospitals | | All Other Hospitals | | Total | |
|---|---|---|---|---|---|---|---|---|
| | Number | Capacity | Number | Capacity | Number | Capacity | Number | Capacity |
| 1909 | 71 | 8,827 | 232 | 189,049 | 4,056 | 223,189 | 4,359 | 421,065 |
| 1914 | 93 | 12,602 | 294 | 232,834 | 4,650 | 287,045 | 5,037 | 532,481 |

HOSPITAL DEPARTMENTS OF INSTITUTIONS

The census of hospitals would not be complete without taking account of the small institutional hospitals maintained by schools, homes and other custodial institutions for the care of their own sick inmates. While there are 434 such hospitals, they have a capacity of 25,421 beds and an average of only 16,249 patients. Evidence seems to show that institutions are hospitalizing their patients in the existing hospitals of the community to an increasing extent.

ALL OTHER HOSPITALS

Hospitals that do not belong in any of the preceding classifications number 76 and have a total capacity of 4,107. They include such hospitals as those for pellagra, goiter, proctology and diabetes, and a few others.

LABORATORIES IN HOSPITALS

Laboratories in hospitals have increased faster than the number of hospitals. This growth can easily be noted in the accompanying table, in which it will be seen that the number of laboratories has mounted from 3,035 in 1923 to 4,233 in 1931, a gain of 39.5 per cent in eight years. In California alone, the number of hospital laboratories increased during the past eight years from 163 to 231; in Georgia from 47 to 86; Illinois, 174 to 250; Kentucky, 44 to 80; New York, 249 to 377; Oklahoma, 49 to 91; Texas, 92 to 215, and Virginia, 48 to 88.

*Laboratories, Roentgen-Ray Departments, Schools of Nursing and Social Service Departments*

| State | Laboratories 1923 | Laboratories 1931 | X-Ray Departments 1923 | X-Ray Departments 1931 | Schools of Nursing 1927 | Schools of Nursing 1931 | Social Service Departments 1931 |

| Totals | 3,035 | 4,233 | 2,841 | 4,615 | 1,814 | 1,788 | 1,044 |

Through the inspection of hospitals, and also by the Council's survey of pathologists and clinical pathologists, it is learned that practically all hospitals of standing—whether they train interns or not—have their laboratory work supervised by competent physician-pathologists.

ROENTGEN-RAY DEPARTMENTS

From 2,841 roentgen-ray departments in 1923 to 4,615 at the present time, or an increase of 62 per cent in eight years, is the record which hospitals have set. The state of New York, which reported 242 roentgen-ray departments eight years ago, now has 401. Large increases are registered for Florida, Kentucky, New Hampshire, Oklahoma, South Carolina, Utah, Vermont and Virginia, each of which has a growth of 100 per cent or more over the number of roentgen-ray departments reported in 1923. Through the inspection of hospitals and correspondence with those which are not inspected we are able to know that the hospitals which had not already made arrangements to have the roentgen-ray work supervised by competent physician-radiologists are rapidly establishing such services.

### SCHOOLS OF NURSING

The number of schools of nursing, as shown in the accompanying table, includes all schools that are approved by their respective state boards of nursing examiners. Schools that are affiliated on a basis approved by the state boards are also included. The figures, which indicate a decline in the number of schools from 1,814 to 1,788, require some study and interpretation. For example, North Carolina is credited with 49 schools in 1931 and with none in 1927, because in the former year the board of nursing examiners in that state had not established its list of accredited schools. A considerable number of hospitals have discontinued their schools of nursing. Some hospitals also have had recognition of their schools withdrawn by their state board of nurse examiners. Arkansas in the past five years has reduced its number of schools of nursing from 26 to 16; Georgia, 44 to 30; Iowa, 54 to 39; Kansas, 57 to 43; Nebraska, 27 to 18; Oklahoma, 36 to 21; Wyoming, 7 to 4, and Texas, with an increase of 28 hospitals for that period, shows a decrease of schools of nursing from 72 to 65.

### SOCIAL SERVICE DEPARTMENTS

This year, for the first time, the census included the social service departments by asking each hospital whether it has such a department. An affirmative reply was made by 1,044 hospitals. No definition or qualification was placed on the term "social service department." As would be expected, New York leads with a total of 176, followed by Pennsylvania with 121; California, 87; Massachusetts, 63; Ohio, 56, and New Jersey, 52.

### PHYSICIANS CONNECTED WITH HOSPITALS

With each annual census, particular attention is paid to the number of physicians connected with hospitals. By the census of 1931, it is learned that 116,363 physicians have hospital connection. Serving as superintendents or administrative officers are 2,346 physicians; interns, 7,054; resident physicians, 4,580, and staff, including regular, consultant and courtesy staffs, and physicians bringing patients occasionally, 102,383. Under interns were included those who were taking their fifth year in medicine, or hospital year; also those who were continuing their internship for a second or third year of additional experience and some who were serving partial terms as interns pending the beginning of their regular internships. Under resident physicians were included those who are receiving training in some specialty as well as those who were engaged on salary to do the work of a resident, whether actually residing in a hospital building or not.

In order to find out the actual number of physicians on the regular, consultant and courtesy staffs, including those who occasionally use the hospital, it was necessary to eliminate duplicates. The Committee on the Costs of Medical Care, using the Council's lists of physicians connected with hospitals in ten representative states in 1928, found by actual count that the duplicate appointments constituted thirty-four one hundredths of the total. Since this factor of duplication is presumably applicable to all states, and since it would not change materially from year to year, the coefficient 0.34 was employed to eliminate duplicates from our 1931 census, which gives a net total of 116,363 physicians connected with hospitals. This is comparable with 90,903 physicians connected with hospitals in 1928.

*Physicians Connected with Hospitals*

| State | Physicians Serving as Superintendents | Interns | Resident Physicians | Staff* | Total, 1931 | Total, 1928 |
|---|---|---|---|---|---|---|
| Alabama | 31 | 35 | 30 | 990 | 1,086 | 950 |

### PHYSICIANS' OFFICES IN HOSPITALS

Inquiry was made as to whether any physicians have offices in the hospital, where they meet their private ambulatory patients in the same way that they see patients in their own offices. This, it is recognized, is different from an outpatient service conducted under the auspices of the hospital. Nine hundred and fifty-three hospitals reported that physicians do see their own private ambulatory patients in the hospital, and it appears that most of these have an office, or office hours, in the hospital. The number of physicians using hospital facilities in this way is 4,510, and the number of ambulatory patients is 731,351.

### HOSPITALS IN THE UNITED STATES POSSESSIONS

Although Alaska, the Canal Zone and the insular possessions of the United States are scattered far and are not dependent on one another, the statistics regarding their hospital service are for convenience shown in one table. Their 202 hospitals are not included in the 6,613 hospitals included in the main report.

Reports were received from 90 registered hospitals in the Philippine Islands as compared to 76 one year ago. The number of hospitals in other territories remains about stationary, with a slight increase in the number of beds and the average daily census of patients.

*Hospitals in United States Possessions*

| | Hospitals | Patients Admitted | Beds | Bassinets | Average Patients | Births |
|---|---|---|---|---|---|---|
| Alaska | 17 | 1,785 | 445 | 45 | 218 | 126 |
| Canal Zone | 10 | 16,605 | 1,986 | 40 | 1,396 | 982 |
| Guam | 1 | 2,777 | 120 | ... | 104 | 90 |
| Hawaii | 42 | 24,693 | 4,328 | 141 | 2,992 | 1,090 |

| Porto Rico | 40 | 5,250 | 2,554 | 88 | 1,750 | 298 |
| Virgin Islands | 2 | ...... | 128 | 12 | 64 | ..... |
| Totals | 202 | 104,844 | 17,901 | 651 | 12,438 | 7,548 |

## OUTPATIENT DEPARTMENTS OF HOSPITALS

Outpatient departments were reported by 2,042 hospitals. The number of visits made by outpatients during the year was told us by 1,361 hospitals, and the total number of visits reported amount to 23,431,382, as compared with 13,804,566 visits by outpatients in 1927. The questionnaire by which these results were obtained simply asked: "Is there an outpatient department, or outpatient clinic, maintained by the hospital?" and if so, "Total number of outpatients last fiscal year. . . . Total visits by outpatients last fiscal year." Purposely, no limit was placed on the size or other qualifications necessary to constitute an outpatient department. The accompanying table of outpatient service by states, comparing 1927 and 1931, serves to show a slight decrease in the number of outpatient departments, but an increase in number of outpatients and the number of outpatient visits during the past five years, the only period for which comparable figures are available.

*Outpatient Service by States—Comparing 1927 and 1931*

| State | Number of Outpatient Departments 1927 | Number of Outpatient Departments 1931 | Number of Outpatients 1927 | Number of Outpatients 1931 | Number of Visits by Outpatients 1927 | Number of Visits by Outpatients 1931 |
|---|---|---|---|---|---|---|

| Pennsylvania | 199 | 191 | 723,640 | 911,651 | 2,163,024 | 2,827,412 |
| Rhode Island | 18 | 15 | 40,788 | 39,587 | 124,499 | 190,531 |
| South Carolina | 18 | 25 | 39,509 | 56,274 | 63,579 | 121,761 |
| South Dakota | 18 | 14 | 22,194 | 11,503 | 50,599 | 70,982 |
| Tennessee | 27 | 34 | 81,343 | 126,903 | 153,281 | 357,680 |
| Texas | 73 | 69 | 196,315 | 182,906 | 179,867 | 455,888 |
| Utah | 8 | 9 | 32,221 | 4,822 | 19,145 | 27,691 |
| Vermont | 10 | 10 | 4,273 | 8,215 | 3,461 | 12,119 |
| Virginia | 40 | 39 | 94,689 | 72,405 | 129,666 | 240,372 |
| Washington | 41 | 31 | 67,953 | 63,440 | 51,680 | 160,740 |
| West Virginia | 28 | 29 | 40,660 | 20,020 | 42,717 | 68,894 |
| Wisconsin | 42 | 39 | 64,893 | 36,123 | 54,543 | 232,412 |
| Wyoming | 11 | 8 | 17,527 | 25,022 | 3,216 | 31,374 |
| Totals | 2,130 | 2,042 | 6,750,388 | 6,962,724 | 13,804,566 | 23,431,382 |

Especially significant is the number of visits per outpatient in 1927 as compared with 1931. In 1927 the 6,750,388 outpatients made 13,804,566 visits, a ratio of one and nine-tenths visits per outpatient. In 1931, the 6,962,724 outpatients made 23,431,382 visits, a ratio of three and four-tenths visits per outpatient. The number of times that a patient goes to the outpatient department measures the efficiency of the work of that department.

*Outpatient Departments of Hospitals According to Number of Visits by Patients During the Year*

| | |
|---|---|
| Outpatient departments having less than 1,000 visits during 1931 | 296 |
| From 1,000 to 4,999 | 385 |
| From 5,000 to 19,999 | 386 |
| From 20,000 to 99,999 | 255 |
| 100,000 and over | 39 |
| Not reporting number of visits | 681 |
| Total outpatient departments reported | 2,042 |

## CLASSIFICATION

(*a*) *Hospitals and Sanatoriums;* (*b*) *Related Institutions.*—In this issue for the second time the list of hospitals registered by the American Medical Association is given in two sections, (*a*) 5,130 hospitals and sanatoriums, and (*b*) 1,483 related institutions.

The related institutions, because of their special or limited nature, do not deserve to be regarded as hospitals but are, so far as we know, entirely ethical and render a needed nursing or medical service to their communities.

Among the related institutions will be noted some that bear the name of general hospitals. The majority of these have been found lacking in some of the services that are usually found in a general hospital.

*Hospitals, Sanatoriums and Related Institutions*

| | Hospitals | Patients Admitted | Beds | Bassinets | Average Patients | Births |
|---|---|---|---|---|---|---|
| Hospitals and sanatoriums | 5,130 | 6,851,403 | 823,744 | 49,283 | 651,983 | 698,328 |
| Related institutions | 1,483 | 304,574 | 150,371 | 2,211 | 123,413 | 10,561 |
| Total registered hospitals | 6,613 | 7,155,976 | 974,115 | 51,494 | 775,396 | 708,889 |

Among the essential features, one or more of which is usually lacking in these small institutions, are adequate laboratory service, staff organization, radiologic service, record system, and consultation to safeguard the best interests of patients.

Among the 6,613 institutions appearing on the registered list are 5,130 hospitals having a capacity of 823,744 beds, and 1,483 related institutions with a total capacity of 150,371 beds.

## HOW THE FACTS WERE OBTAINED

The figures shown in these articles were obtained through: (1) reports made by the hospitals themselves using a form which is ordinarily filled out in the superintendent's office and signed by the superintendent; (2) verification, when necessary, and additional facts, if desired, obtained by special correspondence; (3) by inspection, and (4) finally, the Association's county correspondents, district councilors and others.

The response of hospitals in cooperating with the Association to make the census as complete as possible has been highly gratifying.

HOSPITALS REFUSED REGISTRATION

Not included in any of the lists of statistics in this issue are 490 institutions which because of alleged unethical or criminal practices, admission to their staffs of members who are seriously unqualified, either morally or professionally, flagrant methods of advertising or for other valid reasons, are deemed unworthy of being included in any published list of reputable hospitals. The exclusion of such institutions from the Council's published lists marks the development of an aggressive campaign to establish safeguards against irresponsible or malicious institutions which are a menace to the public. For these reasons, therefore, they are excluded from lists of institutions held out as worthy of receiving the public's patronage. The 490 unregistered institutions have only 14,968 beds.

*Hospitals Not Registered by the American Medical Association*

HOSPITALS AS EDUCATIONAL INSTITUTIONS

Retrenchments which all hospitals have had to make in expenditures as the result of current economic circumstances do not seem to have affected internships in any readily discernible way. More positions are being offered than ever before and the keen competition among hospitals for suitable interns continues. The explanation probably lies in the fact that an intern corps is a relatively small drain on the financial resources of a hospital when the type of service which the interns are prepared to give is considered.

On the other hand, economic conditions are making interns timorous of entering active practice in the face of limited opportunities and strong established competition. We find them remaining longer in hospitals and protracting their term of training as senior interns, assistant residents or the like.

This presentation of statistics reveals 691 approved hospitals offering 6,054 internships. These are the highest figures yet attained. In 1914, when the first accurate statistics on internships were collected by the American Medical Association, 508 hospitals were provisionally approved, in which 2,667 interns were employed. The actual conditions under which interns serve are in much greater contrast than the figures indicate. Eighteen years ago hospitals were not anxious to have interns. Many of them were unmindful of the future importance to medical education of intern training. However, the years witnessed a steady increase in the interest which hospitals were developing regarding internships. This trend is largely explained by the fact that the medical colleges were producing far better qualified graduates, men who because of real ability were welcome within the hospitals. Furthermore, hospitals had for a long time been interested in education, a development first exemplified by the rise in standards for nursing education and the attention that was being focused on hospitals as the principal means for self improvement on the part of the average staff member. In other words, it was not difficult for individual hospitals to develop a consciousness of their true educational importance.

THE AVERAGE APPROVED INTERNSHIP HOSPITAL OF 1932

The table presents in compact form some of the characteristics of the present internship hospital. Six hundred and nineteen hospitals, offering 6,054 openings, compete strongly for the 4,735 members in graduating classes. This is a discrepancy of 1,319 positions as contrasted with 1,019 positions in 1931. These figures tell in realistic fashion the popularity which the intern enjoys in hospitals.

The difference in the totals of columns three and one represents the tendency on the part of hospitals to retain interns for a second year of intern service. Three hundred and eighty-nine interns are employed in excess of the number of graduates. It also represents the willingness of many interns to defer the plunge into actual practice under present conditions.

The figures in the table are presented by states in order to illustrate certain facts about the distribution of interns, where the greatest demand lies for their services and also which localities produce the greatest number. *It will be seen that in most cases the production and demand go hand in hand; that is, the populous centers which need a greater number of doctors usually produce the most. Notable exceptions are Nebraska, which produces four times the actual number of interns that are serving in that state, whereas New Jersey produces none and offers 244 positions.*

The fifth and sixth columns indicate in quite convincing fashion the present incomplete coverage of available clinical material. No intern can successfully serve the number of patients which forty-two beds represent in the average hospital—daily occupancy and average length of stay considered. Some hospitals still require their interns in addition to other duties to maintain acceptable charts on all admissions. The result of this practice is bad from the standpoint both of the records and of the interns. On the one hand the charts are hurriedly and sketchily compiled and on the other the interns develop hasty and slipshod tendencies entirely incompatible with present careful methods of study.

*Characteristics of Internship Hospitals*

| State | Number of Med. Grad. | No. of Internships Offered | No. of Interns (Actual) | No. of Hospitals Approved | Total Bed Capacity App. Hosp. | Beds per Intern | Interns per Hosp. |
|---|---|---|---|---|---|---|---|
| Alabama | ... | 27 | 21 | 4 | 934 | 45 | 5 |

| North Carolina | ... | 35 | 38 | 11 | 1,783 | 47 | 4 |
| North Dakota | ... | 4 | 2 | 2 | 340 | 170 | 1 |
| Ohio | 196 | 305 | 285 | 36 | 11,438 | 40 | 8 |
| Oklahoma | 43 | 31 | 15 | 5 | 1,392 | 96 | 3 |
| Oregon | 59 | 40 | 35 | 5 | 1,450 | 42 | 7 |
| Pennsylvania | 517 | 682 | 597 | 78 | 23,366 | 39 | 8 |
| Rhode Island | ... | 31 | 28 | 4 | 1,250 | 45 | 7 |
| South Carolina | 41 | 24 | 26 | 4 | 693 | 27 | 7 |
| South Dakota | ... | ... | ... | ... | ..... | ... | .. |
| Tennessee | 154 | 84 | 58 | 10 | 2,547 | 44 | 6 |
| Texas | 145 | 108 | 82 | 20 | 5,244 | 64 | 4 |
| Utah | ... | 21 | 19 | 5 | 1,297 | 67 | 4 |
| Vermont | 31 | 5 | 4 | 1 | 145 | 36 | 4 |
| Virginia | 141 | 66 | 66 | 9 | 2,583 | 39 | 7 |
| Washington | ... | 50 | 52 | 13 | 3,304 | 64 | 4 |
| West Virginia | ... | 17 | 20 | 4 | 896 | 45 | 5 |
| Wisconsin | 106 | 130 | 110 | 22 | 5,572 | 51 | 5 |
| Wyoming | ... | ... | ... | ... | ..... | ... | .. |
| Totals | 4,735 | 6,054 | 5,124 | 691 | 213,269 | 42 | 7 |

The comparison between columns six and seven is a further indication that not many hospitals in the United States are overstaffed with interns—if twenty-five beds per intern may be accepted as representing an ideal ratio. Actually a few hospitals do provide more interns than one for each twenty-five beds, but the great majority of institutions do not reach these figures and in some instances are grossly understaffed.

### FUTURE INTERNSHIPS

More and more hospitals each year are asking for approval based on a genuine compliance with the "Essentials of a Hospital Approved for Interns." The necropsy requirement of 15 per cent on hospital deaths, which proved a stumbling block for many, presents no longer any marked difficulty. Other features that are desirable in an educational program must in the future be emphasized. In place of the size of hospitals and actual amount of clinical material, greater consideration may be placed on how the clinical material is used and whether it is sufficiently diversified. Above all, much more complete dependence must be placed on the teaching ability of the staff. The approved internship hospital of the future will no doubt take on more and more the aspects of an organized educational institution with teaching duties designated to capable staff members. Quite possibly a recurring evaluation at periodic intervals of the results being obtained in the training of interns will occur and the correction of obviously faulty or inadequate methods will result. The internship committee is becoming a more and more important body, and none but the ablest staff members should be included in its membership.

### COMPENSATION FOR INTERNS

Reference to the table, which presents the latest available figures, will furnish indisputable proof that compensation in itself is still an unimportant consideration in the choice of internships. It will be noticed that although a greater number of hospitals must pay their interns in order to attract applicants, even so fewer interns are paid. The large hospitals using more interns per hospital usually offer such valuable teaching opportunities as to make the receipt of a salary a minor consideration. The smaller general hospitals in which organized teaching is relatively meager find themselves unable to compete with the larger institutions unless a financial consideration is introduced as an attraction. The best salaries are paid by the service hospitals (army, navy, public health), which are established by government pay tables according to rank and length of service.

*Salaries of Interns in Approved Hospitals, 1923-1930*

| | Number of Hospitals | | | | | Number of Interns | | | | |

### RESIDENCIES IN SPECIALTIES

The hospital internship is not considered in any sense as graduate medical education. It is widely known as the fifth year in medicine, culminating in effective fashion the preceding years in medical school and of demonstrated value as an introduction to the actual practice of medicine. For physicians planning to enter into a specialty, the internship is now considered as a preliminary requirement and is demanded in all recognized postgraduate medical schools.

The hospitals do, however, afford many admirable facilities useful in advanced training. Residencies in specialties as now served by 2,144 men in 372 hospitals exemplify in true fashion the acknowledgment on the part of the younger medical profession of the value of these opportunities.

The usual residency as offered in most hospitals is a continuous twelve months' service under the direct supervision of competent attending physicians, proficient in the theory and practice of the specialty. There can be no doubt that such training is insufficient for the development of sound, safe specialists. The opinion of medical educators, many of whom deplore the present emphasis on specialization, is that such a term of service should be introductory only to the particular clinical branch of medicine, preparatory to or concurrent with study in a recognized postgraduate medical center. In recognition of these obvious facts, some of the leading teaching hospitals, mostly associated with medical schools, require periods of resident service for three, and in a few instances as long as five, years.

Residents, often, are required to teach undergraduates and interns. As may be expected, this is by no means the least effective part of the training of the resident himself. Also, a great deal of confidence can be placed in the quality of instruction which these men impart:

The Council on Medical Education and Hospitals of the American Medical Association approves residencies in twenty-eight specialties, basing its approval on certain well defined principles. It is in entire accord with the view that a residency is in itself no adequate preparation for the practice of a specialty. But the increasing interest manifested in the certification of specialists makes the residency increasingly important. No doubt, the demand for these positions will increase.

---

## ESSENTIALS OF A REGISTERED HOSPITAL

*General Statement.*—The American Medical Association gives recognition to hospitals by admitting to the Hospital Register those that are found to qualify according to the essentials contained in the following paragraphs.

Registration is a basic distinction between all recognized hospitals and those that are refused recognition. It is a prerequisite to the consideration of a hospital for approval for interns or for residencies in specialties.

The registration of hospitals, the approval of hospitals for interns, approval for residencies in specialties, and all other service of the Association regarding hospitals is carried on by the Council on Medical Education and Hospitals.

It is the desire of the Council to cooperate in every way for the improvement of hospital service, whereby the sick and injured may be provided with scientific and ethical medical care.

The Council does not have nor does it assume legal authority over any hospital. It recognizes clearly that the officers in charge of such institutions have the unquestioned right to conduct the hospitals in any way they may deem wise. If a hospital desires to have its name appear on the American Medical Association Hospital Register and thus have the endorsement of that Association, it should be willing to comply with the principles which the Council on Medical Education and Hospitals considers necessary.

*Essentials of a Registered Hospital.*—Hospitals seeking admission to the register should have the following qualifications:

1. *Organization.*—The organization should consist of a board of trustees or other supreme governing body having final authority and responsibility and an executive officer or superintendent to carry out the policies adopted by the governing body. The executive officer should be assisted by adequate competent personnel.

Regardless of the form of organization, the hospital should function primarily in the interests of the sick and injured of the community.

2. *Staff.*—This constitutes the most important essential. The staff should be organized and composed of regular physicians who are properly qualified as to training, licensure and ethical standing.

Staff membership and the use of the hospital's facilities must be limited to doctors in medicine. Where cult practitioners, osteopaths, chiropractors or other healers outside the scope of regular medicine are allowed to use the hospital's diagnostic facilities, to prescribe for or treat patients in the hospital, or to enter orders or other data on the case records, such a hospital obviously cannot be recognized or endorsed by the American Medical Association.

Regular staff conferences should be held at least monthly and preferably more often. All deaths that occur during the period intervening between meetings, perplexing cases, and patients who do not respond to treatment should be discussed. When postmortem examinations have been performed there should be a presentation of the clinical aspect of the patient and the postmortem observations. Interesting pathological specimens from surgery or removed at postmortem should be presented and discussed with regard to the preoperative or antemortem findings.

Minutes of staff conferences should be kept and filed with the hospital records. The activity of the staff as to scientific meetings and clinical and pathologic conferences is an index to the scientific mindedness and progressiveness of the group.

3. *Nurses.*—A competent nursing staff should be provided by employing an adequate number of registered nurses who are graduates of schools of nursing recognized by the state board of nurse examiners, or by maintaining such a school.

All nursing should be supervised by qualified registered graduates.

4. *Records.*—An adequate record system should be maintained. No particular system or set of forms is recommended, since requirements are not the same under varying circumstances. The average case record should include at least a brief medical history, physical examination, laboratory reports, diagnosis, operative record, progress notes, nurses' notes and summary. Case records should be complete in every department and reviewed and signed by the attending physicians before they are placed in the permanent file. Roentgenologic interpretations, pathologic descriptions and diagnoses of tissues removed in the operating room, and (when an autopsy has been performed) a description of postmortem observations, should be included with the patient's record.

Case histories and physical examinations should be recorded in the patient's chart within twenty-four hours after the patient has been admitted to the hospital. A patient should not be operated on, except in the case of emergency, when the history, physical examination and routine laboratory work have not been completely recorded in the chart. The duty of recording these data falls on the attending physician and he should be held directly responsible for the case records.

Monthly and annual analyses of hospital service should be made in order that the staff may be in a position to improve its service.

5. *Pathology.*—All tissues removed in the operating room should be examined, described and diagnosed by a competent pathologist excepting tissues, such as tonsils and teeth, in which the pathologic changes are quite obvious.

A physician-pathologist should be employed on a full time or part time basis. When this is not practicable, arrangements should be made with a consulting pathologist for tissue diagnosis, postmortem work and the interpretation of the more complicated tests and determinations in clinical and surgical pathology, as well as in general clinical laboratory work. The pathologist preferably should be one listed by the Council on Medical Education and Hospitals of the American Medical Association. The Council's list of physicians specializing in clinical pathology or pathology is available on application.

*Autopsies.*—Every effort should be made to secure consent for autopsies, which should be performed by a pathologist or the best qualified other physician available.

6. *Radiology.*—The hospital should provide or have ready access to radiologic equipment and service. When a full time or part time physician-roentgenologist cannot be employed, the services of such a consultant should be secured. Radiologic interpretations must be made only by a competent roentgenologist. A description of the roentgenologic examinations should be placed in the patient's chart. The physician-roentgenologist preferably should be one listed by the Council on Medical Education and Hospitals of the American Medical Association.

A list of physicians specializing in radiology and roentgenology is available on application.

7. *Ethics.*—In order that a hospital may be eligible for registration it will, of course, be expected that the staff and management conform to the principles of medical ethics of the American Medical Association with regard to advertising, commissions, division of fees, secret remedies, extravagant claims, overcommercialization and in all other respects.

# HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,613 hospitals, sanatoriums and related institutions that are located in the United States and 202 in the insular possessions. It omits the names of 490 hospitals which, after investigation, were not accepted. The inclusion of the name of any institution may be taken as an indication that evidence concerning irregular or unsafe practices in that institution has not come to the attention of the Council on Medical Education and Hospitals. For convenience, the list in each state is given in two sections: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include nursing homes, school infirmaries, prison infirmaries, custodial and other institutions designed to give some medical, nursing or convalescent care in an ethical and acceptable manner, but not strictly hospitals; also some general hospitals lacking certain essentials. In the statistics the two classifications are consolidated.

## KEY TO SYMBOLS AND ABBREVIATIONS

★ Approved for general internship, the fifth year in medicine, by the Council on Medical Education and Hospitals.

+ Approved for residency in a specialty for graduates in medicine who have already had a general internship or its equivalent in practice.

◊ School of nursing accredited by board of nurse examiners for state in which it is located.

⊙ Affiliated for nurse training on state accredited basis.

■ Accepts Negro patients (not applicable to nervous and mental hospitals).

▲ Department for mental patients.

The column headed "Type of Service" tells what diseases or conditions are treated in each institution, as follows:

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Chil | Children's | Epil | Epileptic | Iso | Isolation | N&M | Nervous and mental |
| Conv | Convalescence and Rest | EENT | Eye, Ear, Nose and Throat | Inst | Institutional | Ortho | Orthopedic |
| Chron | Chronic | Gen | General | Mater | Maternity | Sk&Ca | Skin and Cancer |
| Dr&Al | Drug and Alcoholic | Indus | Industrial | MenDef | Mentally Deficient | TB | Tuberculosis |

The column headed "Control" indicates for each institution the ownership, control, or auspices under which it is conducted as follows:

| | | | | | |
|---|---|---|---|---|---|
| Cy&Co | City and County | Indian | U. S. Indian Service | Part | Partnership |
| Fed | Federal | Indiv | Individually owned | USPHS | United States Public Health Service |
| Frat | Fraternal | Indus | Industrial | VetAd | Veterans Administration |
| Indep | Independent hospital association | | | | |

## HOSPITAL SERVICE IN THE UNITED STATES

In 1873 there were apparently in the United States 178 hospitals with a total capacity of 35,604 beds. Today there are 6,613 hospitals with a total capacity of almost a million beds. The development of hospitals has been one of the most astounding growths witnessed in this country of astounding expansions. It represents, no doubt, the reply of scientific medicine and its correlated professions to the demand of an intelligent public for the best type of medical care.

Today, as revealed by the exceptionally complete report presented in this issue of THE JOURNAL, there are numerous varieties of hospitals from the points of view of management, ownership, facilities and many other aspects. The federal government has gone into the hospital business in a big way. The individual states have increased their hospital capacity in five years by more than 60,000 beds. The county hospitals have increased by 28 in number and by 15,000 beds. The city hospitals care for more patients than in 1929. Moreover, there are church hospitals, fraternal hospitals, industrial hospitals, individual and partnership hospitals, and hospitals conducted by independent associations. There are vast numbers of general hospitals, indeed, about two thirds of the total number; but there are also large numbers of hospitals for nervous and mental disease, for tuberculosis, for infectious disease and for children, for eye, ear, nose and throat, and for orthopedics. Then, too, there are convalescent and rest hospitals and industrial hospitals. These institutions are in general conducted on an exceedingly high plane. Practically every hospital of any standing whatever has its laboratory work supervised by competent physician pathologists, and more than 75 per cent of all hospitals have good x-ray departments. There was a time when a relatively small number of physicians made use of hospital facilities. There are today approximately 150,000 physicians in the United States, and more than 116,000 have hospital connections. Moreover, hospitals have inclined toward recognition as medical centers. There are almost a thousand hospitals which report that physicians see their private patients in the hospital and that they have offices or office hours in the hospital.

The careful survey made by the Council on Medical Education and Hospitals of the American Medical Association yields the names of 490 institutions which have not been admitted to the list because of alleged unethical or criminal practices, or because of admission to their staffs of members not qualified, or because of forms of practice so flagrantly beyond the principles of fair conduct that they could not be admitted to such a list or for other valid reasons. In the 490 institutions barred from recognition there are about 15,000 beds. On page 2077 of this issue of THE JOURNAL appear the essentials of a registered hospital. The careful reader will find here promulgation of a standard that has been largely responsible for bringing the hospitals of this country to their present high state.

The hospital privately owned and operated for profit has come upon sad days. The increasing cost of care for difficult or surgical cases, due to the development of modern scientific methods and the requirement of extensive personnel, has made hospitals increasingly dependent on endowment. Bed costs per day have risen from a dollar or two to four and five or even ten dollars per day in some institutions. Thus hospitals operated for profit continue to decline in number rapidly. Five years ago such institutions made available 39,118 beds; now they offer only 36,764 beds. Moreover, the average number of patients cared for dropped from 21,779 to 17,912; with such a decrease the number of individual and partnership hospitals is likely to be still further diminished during the present financial emergency.

It is no secret that, except for the charity hospitals of this country and those conducted by various governmental agencies, the hospitals of the country are suffering because of the lack of occupancy of many beds. Indeed, government hospitals may be classified in the charity group, because they occasionally accept fees or give free care to many a patient well able to pay. Some private hospitals are less than half occupied. A general average would indicate 40 per cent empty beds in most private institutions. Since such institutions are largely dependent on endowment and donations as well as on the fees coming from patients, their situation is today a serious one. The people of this country built these hospitals to meet their needs and, in many instances, have made notable sacrifices to maintain them. It would be pitiful indeed if these institutions were allowed to disappear in this time of emergency when any means could be found for maintaining them through what has been called our "predicament." Because of the emergency there has been increasing call on the facilities of federal, state, county and municipal hospitals. Many of them have been filled to the capacity of their equipment. Under these circumstances cries have come from the bureaucrats, big and little, for increased funds to be raised by taxation or by the issuing of bonds for the enlargement of such institutions. The people of our country must well consider whether it would not be for the greater good to apply available federal, state, county and municipal funds to the utilization of the vacant beds in private institutions.

## THE HISTAMINE FACTOR IN ANAPHYLAXIS

The well defined differences in the anaphylactic syndrome in different species of animals suggests the necessity of developing various antianaphylactic therapies. This, however, would not be necessary if it could be shown that the experimental symptomatologies are but quantitative variants of the same basic clinical picture. Numerous experimenters have attempted to establish this basic unity. It has been suggested, for example, that the exceptionally high development of the bronchial musculature in the guinea-pig is the reason why anaphylaxis in this animal is of the asthmatic type. The unusually developed musculature of the hepatic veins of dogs is suggested as a reason why canine anaphylaxis is of the splanchnic-congestive type. Other experimenters have emphasized basic factors in the capillary endothelium and in the circulating blood.

A convincing contribution to this theory of clinical anaphylaxis is contained in Watanabe's[1] recent quantitative determinations of the comparative topographic distribution of histamine-like substances in the organs of different animal species, and the variations in this distribution as a result of specific sensitization and specific protein shock. Alcohol-soluble, histamine-like "tissue hormones" were extracted from the organs and titrated by means of the isolated guinea-pig intestine, the titrations being recorded in terms of histamine equivalents. Watanabe reports that normal guinea-pig lungs contain the equivalent of 14.2 mg. of extractable histamine per kilogram. Normal guinea-pig liver, however, is relatively "histamine" free, yielding but 1.3 mg. per kilogram. As a result of specific sensitization (horse serum) the alcohol-extractable, histamine-like factor of the lungs increases fivefold by the twelfth to the twentieth day after injection of the sensitizing dose, but there is no parallel increase in the "histamine" content of the liver. In normal dogs, Watanabe reports the physiologic equivalent of 22.5 mg. of histamine per kilogram of pulmonary weight, with twice this amount, or 44.7 mg., in the liver. As a result of sensitization, the canine lung "histamine" is not increased. The canine liver "histamine," however, is doubled (the eighteenth to twentieth day average being 80 mg.).

The anaphylactic reaction in both animal species is accompanied by an explosive reduction in this excessive tissue "histamine." In guinea-pig lungs, for example, the extractable "histamine" falls from its sensitivity level (73 mg.) to 3 mg. per kilogram. This apparent pulmonary release of "tissue hormone" into the blood stream is sufficient to maintain the liver "histamine" at its preshock level (1.3 mg.). In dogs, the explosive release reduces the liver "histamine" from 80 mg. to 20 mg. The 60 mg. presumably given off into the blood stream is apparently sufficient to raise the pulmonary "histamine" from 20 mg. to 30 mg. per kilogram. Similar though less pronounced secondary rises are noted in the spleen and the myocardium. The large amount of histamine-like substance released from the hypersensitive hepatic parenchyma of dogs, and the absence of this release in guinea-pigs, may well account for the different symptomatologies in the two species.

That the liberation of a histamine-like tissue factor either from the lungs or from the liver is not an essential part of the anaphylactic reaction, however, is indicated by the rapid decrease in the "histamine" excess in guinea-pig lungs after the twentieth day of sensitization. By the seventieth day the "histamine" has fallen to its presensitivity level. Little reduction, however, has yet taken place in protein sensitivity. Analogous assays, however, have not yet been reported for experiments on dogs.

There is, of course, nothing new in thus regarding "explosive histaminemia" as a secondary or nonessential anaphylactic phenomenon. Perfusions, transfusions and organ transplantations in dogs have already led American investigators[2] to the same conclusion. Nevertheless, Watanabe's biochemical assays are a distinct contribution to anaphylactic study.

## THE VETERAN AND THE HOSPITAL

Our federal hospitals have today a total capacity of 69,170 beds and 391 bassinets. Of these, the hospitals of the Veterans' Administration have a total capacity of 28,454 beds. These institutions are located, as will be seen from the report on page 2064 in this issue of The Journal, in various parts of the United States. There are thirteen states which do not have any veterans' hospitals. As is stated in our editorial on hospitals, the number of vacant beds in private institutions is cause for great concern to all those associated with the maintenance of these hospitals. Previous editorials in The Journal have indicated the desirability that these beds be utilized by the Veterans' Administration for the care of veterans who are awaiting admission to its hospitals, and particularly for the care of general medical and surgical cases with a view to making available in veterans' hospitals beds for tuberculous and psychiatric cases.

The medical profession of this country does not yield to any other group in its desire to see that those who gave of their best to our country in its time of need receive the best type of medical care in their time of illness and distress. The reputation of the medical profession so far as concerns proper medical care of the poor has been established through many centuries of practice. Never has the physician hesitated to give ungrudgingly of his time and of his skill for those in need. Obviously, he would hesitate still less if called on to care for any one who had served the country in military or naval warfare. Nevertheless, it has been argued that the desire of the physician to have the Veterans' Administration use the available beds in civilian hospitals and the available services of private physicians is animated primarily by a pecuniary motive. The insinuation is intolerable because based on a misunderstanding of the motivation and particularly because it comes from those who must themselves benefit both in money and in prestige by a maintenance of the present situation. The medical profession of this country has given intensive study to the question of the provision of the best type of medical care, not only for the veteran but also for our citizenry in general. It is the opinion of the vast majority of physicians that the best type of medical care in 90 per cent of the illnesses that afflict mankind is to be had at the hands of the family physician and preferably in an institution in the community in which the sick man or his family resides. Certainly, it would seem to be well within reason that the Veterans' Administration realize the importance of this observation and that it arrange so far as general medical and surgical cases are concerned to provide the veteran in his hour of need with this type of medical care. Every one realizes the desirability of institutional care for the tuberculous and the psychiatric patient.

[2] Manwaring, W. H., and others: J. Immunology **10**: 567, 575 (May) 1925.

The defense of officials of the Veterans' Administration to the arguments here set forth has seemed inadequate to all who are familiar with the situation. It has been argued that private physicians and private hospitals exploit the veteran and that the funds necessary for such private care are beyond those necessitated by care in a veterans' hospital. Opposed to this argument is the fact that the veteran in a veterans' hospital is far removed from his home, so that the extra cost of transportation and of maintenance during transportation must be assessed in the total cost of care. Next, the veteran when he enters a veterans' hospital at once receives a total disability allowance approximating $80 a month and is kept in a veterans' hospital for a number of days beyond that required when similar cases are cared for in private institutions. Incidentally, a Civil War veteran or a Spanish-American War veteran has his compensation reduced when he enters a veterans' hospital. Here is a matter for early adjustment by Congress! Finally, even if the costs of private medical care should be shown by proper investigation to be slightly beyond those of care in a veterans' hospital, the advantages of private care in maintaining self respect, in preventing pauperization and particularly in holding together homes which are otherwise subject to dissolution are not to be weighed in dollars and cents.

The American Medical Association, through its Committee on Legislative Activity, its Board of Trustees and its officers, has endeavored to give earnest cooperation to the American Legion in reaching a mutual aim; namely, proper medical care for every veteran meriting that care. The conferences that have been held by the representatives of the American Legion, representatives of the Association and, more recently, of the Veterans' Administration, lead to the opinion that such a solution must come and it is good to know that the conferences are to be continued in the future. Moreover, legislation before Congress indicates a desire on the part of the government to restudy the situation and to work out a uniform plan that will be for the best interest not only of the veterans but also of the people and of the medical profession and hospitals of this country.

## ALCOHOL IN NORMAL TISSUES

Physiologic chemistry deals in part with the chemical reactions that occur in the body in connection with the digestion of food, oxidations, metabolism and detoxication. For all these processes type equations can be written which, experience has shown, represent the main trend of the reactions. It is recognized, however, that the main biochemical transformations are generally accompanied by side reactions, which may at times assume considerable importance. Recent evidence bearing on this point has been furnished by Gettler and his co-workers,[1] who succeeded in isolating pure anhydrous ethyl alcohol from human and animal tissues. The aqueous suspension of ground tissue or of blood was distilled with steam, and the alcohol together with organic acids, bases and other volatile compounds was collected in the distillate. The recovery of the alcohol from the highly diluted solution thus obtained required the construction of special distillation flasks, condensers and rectifier, the use of which resulted after "a single distillation of a few drops of very high proof alcohol, b. p. 78 to 79°." This was dried, redistilled and finally fractionated, the contaminating compounds being removed during the procedure. The boiling point and percentage of carbon as well as the constants of two esters formed from the alcohol proved that the material was ethyl alcohol. Special care was taken to be sure that no alcohol had been used within two weeks of the time when the human tissues were taken. The quantity obtained from human brain was 0.0004 per cent, from human liver 0.0026 per cent, from human blood 0.004 per cent, and from the dog's brain, liver and blood 0.003 per cent, 0.0007 per cent and 0.0013 per cent, respectively. These studies illustrate again the possibility of securing unsuspected information when suitable methods become available. They also emphasize the intimate, normal association of alcohol with man's vital activities.

## MEDICAL BROADCAST FOR THE WEEK

### American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 1:30 to 1:35 p. m. over Station WBBM (770 kilocycles, or 389.4 meters) of the Columbia Broadcasting System. The Columbia Chain Program has been discontinued for the present.

The program for the week is as follows:

June 13. How Sick Are You?
June 15. Worthwhile Week-Ends.

There is also a fifteen minute talk sponsored by the Association on Saturday from 11:15 to 11:30 a. m., over Station WBBM.

The program for the week is as follows:

June 18. Goiter.

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time.

---

# Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

## ARKANSAS

**Society News.**—The First Councilor District Medical Society and the Northeast Arkansas Medical Society were addressed, April 21, at Walnut Ridge, by Drs. Walter O. Parrish, Rector, on "Trend of Present Day Medicine"; Grady W. Reagan, Little Rock, "Etiology, Prevention and Treatment of Urethral Stricture," and Henry G. Hill, Memphis, "Fractures."

## CALIFORNIA

**Dr. Marriott to Lecture.**—Dr. W. McKim Marriott, dean and professor of pediatrics, Washington University School of Medicine, St. Louis, will be the lecturer at the University of California Medical School for the year 1932-1933. Dr. Marriott, who will be at the medical school early in the fall of this year, will conduct lectures and clinics.

**Changes at University Medical School.**—The following changes at the University of California Medical School have recently been announced, among others:

Dr. Francis S. Smyth, professor of pediatrics, San Francisco.
Dr. Ian Maclaren Thompson, professor of anatomy, Berkeley.
Dr. Robert O. Moody, professor of anatomy, Berkeley.
Dr. Sidney J. Shipman, associate clinical professor of medicine, San Francisco.
Dr. Robert S. Stone, associate professor of roentgenology, San Francisco.
Dr. Norman N. Epstein, assistant professor of dermatology, San Francisco.
Laurence Gahagan, assistant professor of psychology, Los Angeles.
Joseph A. Gengerelli, Ph.D., assistant professor of psychology, Los Angeles.
Dr. Lewis F. Morrison, assistant professor of otology, rhinology and laryngology, San Francisco.
Dr. Benjamin L. Friedlander, to assistant clinical professor of medicine.

**Fraudulent Reports on Veterans.**—*California and Western Medicine* has recently published newspaper reports of an alleged "racket," wherein physicians have been signing false affidavits of examination of veterans applying for disability compensation. Dr. William E. Glaeser, San Francisco, is said to have been sentenced to a year in jail and a fine of $1,000. Later, however, the judge announced that if the physician would pay $1,100, the amount obtained by the veteran in the case, he would suspend the jail sentence. The fine was paid and the physician was released. Drs. Fred H. Van Tassell and Aubrey H. Staples, both of Oakland, were sent to the county jail for one year when their probation pleas failed after they had pleaded guilty to fraud in veterans' cases. The physicians examined several veterans in 1927, it was reported, but made affidavit that they made the examinations in 1925. Dr. John R. Vasko, Alameda, and Elmer J. Johnson were sentenced on charges of fraud recently. Dr. Vasko is said to have sworn falsely to an affidavit which declared that a war veteran at Livermore contracted tuberculosis before 1925. Dr. Vasko was sentenced to a month in the Alameda County Jail and fined $500. The veteran was given three months in the county jail.

## CONNECTICUT

**State Medical Meeting.**—Dr. William A. La Field, Bridgeport, was elected president of the Connecticut State Medical Society, May 26, and Dr. Charles W. Comfort, Jr., New Haven, reelected secretary. The next annual session will be held at Hartford, May 24-25, 1933. The scientific program at the recent meeting in New Haven was given, among others, by Drs. Robert Salinger, New Haven, on "Prophylaxis of Rheumatic Fever"; Arial W. George, Boston, "Value of the Use of X-Rays in the Study of the Lower Back and Sacrum in Industrial Accident Cases"; Cornelius V. Kilbane, New York, "Radiological Aspects of Cardiac Diagnosis"; Webb W. Weeks, New York, "Operative Procedures of Choice in Secondary Glaucoma"; John McCoy, New York, "Nasal Polypi"; William F. Verdi and Charles T. Flynn, New Haven, "Tumors of the Upper Air and Food Passages"; Louis Antupit, Hartford, "Intestinal Obstruction: A New Method of Treatment"; Louis H. Nahum, New Haven, "Chemical Changes in the Heart in Coronary Occlusion"; Robert G. Urquhart, Uncas-on-Thames, Norwich, "Thoracoplasty"; Ruth F. Wadsworth, New Canaan, "Contact with the Laity Through Broadcasting, Press, and Advertising Supervision"; Charles Ricksher, Middletown, "Modern Treatment of the Insane"; Roy L. Leak, Middletown, "Commitment of the Insane"; George R. R. Hertzberg, Stamford, "Camphorated Oil in Surgery," and Arthur H. Morse, New Haven, "Female Sex Hormones." A symposium on kidney disease and pregnancy was conducted by Drs. John P. Peters and Abraham Nowell Creadick, both of New Haven. Dr. Charles C. Gildersleeve, Norwich, gave the presidential address.

## GEORGIA

**State Medical Election.**—Dr. Marvin M. Head, Zebulon, was installed as president of the Medical Association of Georgia at its annual session in Savannah, May 20, and Dr. Charles H. Richardson, Jr., Macon, was chosen president-elect. The vice presidents are Drs. Arthur A. Morrison, Savannah, and David H. Garrison, Tate. Macon was selected as the city for the next meeting of the association, May 9-12, 1933.

## IDAHO

**Annual Registration Due July 1.**—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to be registered annually on or before July 1, with the Department of Law Enforcement, and at that time to pay a fee of $2. If a licentiate has not paid the annual registration fee by October 1, his license can be canceled and will be restored thereafter only on payment of the delinquent fees and a $10 penalty.

## ILLINOIS

**State Medical Election.**—Dr. John R. Neal, Springfield, was inducted into office as president of the Illinois State Medical Society at its annual meeting in Springfield, May 20. Dr. Philip K. Kruescher, Chicago, was named president-elect. Other officers of the society are Drs. Don W. Deal, Springfield, and Charles E. Wilkinson, Danville, vice presidents, and Drs. Harold M. Camp, Monmouth, and A. J. Markley, Belvidere, secretary and treasurer, respectively. The next annual meeting of the society will be held in Peoria.

**Personal.**—Dr. Charles L. Tegtmeier, Freeburg, has been appointed district health officer, succeeding his brother, the late Dr. Edward H. Tegtmeier, Millstadt. Dr. Tegtmeier has practiced in Freeburg for twenty-four years. He served as mayor of the city for three terms and was village health officer for fifteen years. He will have charge of state health activities in the counties of St. Clair, Madison, Monroe, Clinton, Washington, Randolph and Perry.——Dr. Martin H. Seifert has been appointed health commissioner of Wilmette, succeeding Dr. Winfred W. Hawkins, resigned.

### Chicago

**Institute Dissolves Medical Advisory Board.**—The Chicago *Tribune* reported, June 4, that the medical advisory board of the Public Health Institute had been dissolved by the board of trustees.

**Fund for the Arno B. Luckhardt Fellowship.**—Dr. Anton J. Carlson, chairman, department of physiology, Graduate School of Medicine of the Division of Biological Sciences of the University of Chicago, gave the initial contribution toward a fund of $30,000 to provide a fellowship in honor of Dr. Arno Benedict Luckhardt, professor of physiology in the school. In making the contribution, Dr. Carlson wrote to the president of the university as follows: "I have had under consideration for some time the establishment of a fellowship in recognition of Dr. Luckhardt's outstanding services in research and teaching in the medical sciences, the appointment to the fellowship to be vested in the department of physiology of the university . . . it is planned that the fellowship is not to be awarded until the fellowship fund reaches $30,000 or more so that the annual amount of the fellowship will be at least $1,500."

## INDIANA

**Course for General Practitioners.**—The Indiana State Medical Association will conduct a course of instruction for general practitioners, June 16-17, at City Hospital, Indianapolis. Among the instructors will be Drs. Charles A. Doan, professor of medical and surgical research, Ohio State University College of Medicine, Columbus, on "Mechanism of Blood Formation and Its Relationship to Diagnosis and Therapy"; Beaumont S. Cornell, Fort Wayne, "Clinical Features of Pernicious Anemia"; Leon G. Zerfas, assistant professor of medicine, Indiana University School of Medicine, Indianapolis, "Treatment of Anemia"; Roger S. Morris, professor of medicine, University of Cincinnati College of Medicine, Cincinnati, "Cardiovascular Diseases"; Floyd T. Romberger, La Fayette, "Anesthesia for the General Practitioner"; William J. Dieckmann, Chicago, "Toxemia in Pregnancy"; Williams McKim Marriott, dean and professor of pediatrics, Washington University School of Medicine, St. Louis, "Infant Feeding"; Joseph L. Miller, clinical professor of medicine, Graduate School of Medicine of the Division of Biological Sciences, University of Chicago, Chicago; Albert E. Bulson, Fort Wayne, and Henry O. Mertz, Indianapolis, a symposium on the kidney—urinalysis and blood chemistry, and William J. Moenkhaus, Ph.D., professor of physiology, Indiana University School of Medicine, Indianapolis, "Physiology of the Heart." Heart clinics will be conducted by Drs. Robert M. Moore, George S. Bond and Edgar F. Kiser, all of Indianapolis. Practical demonstrations in the treatment of fractures will be given by Dr. William R. Davidson, Evansville, and Dr. Garland D. Scott, Sullivan, and Albert Stump, Indianapolis attorney, will discuss "Medicolegal Aspects of Malpractice Suits in Fracture Cases."

## IOWA

**State Medical Election.**—Dr. William W. Bowen, Fort Dodge, elected first vice president of the Iowa State Medical Society at the annual session in Sioux City, May 6, advanced to the presidency following the death, May 7, of Dr. Bert L. Eiker, Leon, incoming president of the society. Dr. Charles B. Taylor, Ottumwa, was named president-elect at the annual session. Dr. Elliott C. Cobb, Sioux City, second vice president, will succeed Dr. Bowen as first vice president, and the second vice presidency will remain unfilled. The next annual meeting will be held in Des Moines.

## MARYLAND

**Memorial to Dr. Jones.**—A committee has been formed to arrange for a memorial to Dr. C. Hampson Jones, for many years health commissioner of Baltimore, with Dr. Huntington Williams, director of health, as chairman. Other members are Drs. John Frederick Hempel, assistant commissioner of health; George W. H. Hemmeter, Frank C. Marino and Anthony L. Rettaliata, health officers, and three lay members of the city health department. The memorial will take the form of an oil portrait of Dr. Jones, to be placed in the health department offices.

**Study of Tuberculosis in Children.**—Since 1928, a clinic at the Harriet Lane Home, Johns Hopkins Hospital, Baltimore, has been conducting a special survey of tuberculosis in children under 2 years of age, who will be kept under observation continuously until they are adults. The objectives include the sources of infection, relationship of childhood infection to outbreaks of pulmonary tuberculosis in later life, racial susceptibility, pathologic studies of the disease, incidence in healthy infants, variations in allergy over a period of years as determined by the reactivity to tuberculin, and protection of infants through the injection of dead tubercle bacilli according to the method of Langer. At present the clinic has under its charge 276 children. Those cooperating in the study include Drs. John C. Gittings, formerly professor of pediatrics, University of Pennsylvania School of Medicine; Wade H. Frost, professor of epidemiology in the school of hygiene at Johns Hopkins University School of Medicine, and Edwards A. Park, professor of pediatrics at Johns Hopkins.

## MASSACHUSETTS

**Health at Lowell.**—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended May 28, indicate that the highest mortality rate (18.3) appears for Lowell, and the rate for the group of cities as a whole, 11.2. The mortality rate for Lowell for the corresponding week last year was 10.9, and the group of cities, 11.2. The annual rate for eighty-five cities for the twenty-one weeks of 1932 was 12.3, as against a rate of 13.3 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

## MICHIGAN

**Physicians Honored.**—The Ingham County Medical Society gave a banquet, May 12, to three physicians who had been members of the organization for forty years. The physicians are Drs. Harry A. Haze, George F. Bauch and Robert E. Miller, all of Lansing. Dr. Fred J. Drolett was toastmaster at the dinner, and the speakers included Mayor Peter F. Gray, the Rev. John O'Rafferty, and Rev. Edwin W. Bishop, Lansing. A musical program was provided.

**Graduate Fortnight.**—The Michigan State Medical Society and the department of postgraduate medicine of the University of Michigan are conducting a graduate fortnight in proctology at the University Hospital, June 6-18. While emergency and office treatment, requiring a minimum of experience and equipment, will be emphasized, the announcement states, conditions that require more highly specialized methods in both diagnosis and treatment will be demonstrated. The fee for the course is $35. Further details may be obtained from the department of postgraduate medicine, University Hospital, Ann Arbor.

## MISSOURI

**State Medical Election.**—At the annual meeting of the Missouri State Medical Association, May 25, Dr. Joseph W. Love, Springfield, was installed as president, and Dr. Warren L. Allee, Eldon, was chosen president-elect. Dr. Edward J. Goodwin, St. Louis, was reelected secretary. The next annual session of the society will be held in Kansas City.

**Personal.**—Dr. William H. Allen, Rich Hill, was guest of honor at a meeting of his friends, May 1, in celebration of his birthday. Dr. Allen has practiced medicine in Rich Hill for fifty-seven years and is an honor member of the Bates County Medical Society and of the state medical association.——Mr. Frank K. Fenwick, a lawyer, has been appointed director of medical licensure to succeed Dr. Ross Hopkins, Jefferson City.

## NEBRASKA

**State Medical Election.**—Dr. Adolph Sachs, Omaha, was named president-elect of the Nebraska State Medical Association at the annual meeting in Lincoln, May 26. Dr. Arthur E. Cook, Randolph, was installed as president and Dr. Roy B. Adams, Lincoln, reelected secretary. The next annual meeting will be in Omaha.

## NEW HAMPSHIRE

**State Medical Election.**—Dr. Harry O. Chesley, Dover, was elected president of the New Hampshire Medical Society at the annual meeting in Manchester, May 18, and Dr. Robert J. Graves, Concord, vice president. Dr. Dennis E. Sullivan, Concord, was reelected secretary. The next annual session will be held at Manchester.

**Unlicensed Practitioner Fined.**—Jesse M. Solomon pleaded guilty in the municipal court of Concord, May 6, to a charge of practicing medicine without having a certificate of registration. He was fined $100, ordered to pay court costs of $35, and sentenced to three months in the house of correction. The latter sentence was suspended when he paid the fine and costs.

## NEW JERSEY

**Medal to Dr. Theobald Smith.**—The Council of the Royal Society of Tropical Medicine and Hygiene at its annual meeting, June 16, will award the Manson Medal to Dr. Theobald Smith, Princeton, director emeritus of the department of animal pathology, Rockefeller Institute for Medical Research, New York. The award is made "for fundamental observations and experiment—the first of their kind—on the transmission of a blood-inhabiting protozoon by a blood-sucking arthropod and for many contributions to knowledge which are of world-wide importance." Dr. Smith retired from the directorship of the department of animal pathology in 1929, when he reached the age of 70. He had occupied the position since 1915, having come to the institute from Harvard, where he had been professor of comparative pathology since 1896. Dr. Smith has continued his association with the Princeton laboratories of the institute.

## NEW MEXICO

**State Medical Meeting and Election.**—The semicentennial meeting of the New Mexico Medical Society was held in Santa Fe, May 19-21, under the presidency of Dr. Fred D. Vickers, Deming. Guest speakers on the program were Drs. Willis S. Lemon, Rochester, Minn., on "Biological and Clinical Aspects of Tuberculous Pleurisy with Effusion"; Cullen W. Irish, Pasadena, Calif., "Neurological Diagnostic Criteria in Abscess of the Brain"; William C. Menninger, Topeka, Kan., "Psychiatry"; William D. Sansum, Santa Barbara, Calif., "Treatment of Underweight, Indigestion and Allergy"; Earl D. McBride, Oklahoma City, "Arthritis"; Albert Soiland, Los Angeles, "Management of Cancer of the Breast"; Clarence G. Toland, Los Angeles, "Object of Formation of Cancer Commission of State Medical Societies"; Hugh T. Jones, Los Angeles, "Bone Tumors"; James W. Hendrick, Amarillo, Texas, "Adenomatous Goiter"; Robert A. Duncan, Amarillo, "Brain Abscess from the Otologist's Viewpoint." Dr. Henry A. Ingalls, Roswell, was chosen president-elect and Dr. Leo B. Cohenour, Albuquerque, secretary. The 1933 meeting will be held in Roswell.

## NEW YORK

**State Medical Election.**—Dr. Frederick H. Flaherty, Syracuse, was chosen president-elect of the Medical Society of the State of New York at the close of the annual meeting in Buffalo, May 24. Other officers elected were Drs. Arthur S. Chittenden, Binghamton, and William Ross Thomson, Warsaw, vice presidents, and Drs. Daniel S. Dougherty and Frederic E. Sondern, both of New York, reelected treasurer and secretary, respectively.

**Society News.**—Dr. Russell L. Cecil, New York, addressed the Medical Society of the County of Albany, at Albany, May 17, on "The Arthritis Problem," and Dr. Arthur Krida, New York, on "Surgical Treatment of Arthritis."——Dr. Ward J. MacNeal, New York, addressed the Madison County Medical Society, Oneida, May 21, in the afternoon, on "The Relation of Laboratory to General Medicine," and the Oswego County society at Fulton on the same subject in the evening.——Dr. Jacob M. Gershberg, New York, addressed the Saratoga chapter of the International Spanish-Speaking Association of Physicians, Dentists and Pharmacists, May 24, on longevity according to the theory of Metchnikoff.

### New York City

**Board Recommends Ban on Radium Waters.**—The medical advisory board of the city department of health, after a special meeting to consider the public health aspects of so-called radium waters, has recommended that the department issue a warning concerning their use. The administration of these waters should be watched over by a physician, who should examine the patient from time to time to make certain that there is no accumulation of radioactive minerals in the tissues, the board advised. There has been much commercial propaganda in recent years alleging the curative powers of radioactive waters. Some of these were shown to be frauds because they had no radioactivity, but a few contained radioactive minerals in solution, it was said. The majority of radium waters used by the public are those charged with radium emanations produced by various devices sold at prices ranging from $3.50 to several hundred dollars. It was the opinion of authorities who conferred with the board that the drinking of water containing radioactive minerals was extremely dangerous and that a ban should be placed on the sale of these waters to the public.

**Academy Recommends Investigation of Veterans' Legislation.**—Congressional investigation of the whole plan of veterans' relief was demanded in a statement recently issued by the committee on public relations of the New York Academy of Medicine. Declaring that the elimination of subsidies to ex-soldiers who are not suffering from war disabilities would reduce federal expenditures more than $450,000,000 a year, the committee made the following recommendations:

1. That hospitalization of veterans for nonservice-connected disabilities be discontinued.
2. That as hospital beds become vacant, the hospitals be sold to the states to be used as public institutions for persons with chronic ailments.
3. That inquiry be made as to adequacy of compensation to widows and dependents of soldiers who died or were killed in the World War or as a direct result of it.
4. That adequate compensation be continued for veterans who are actually diseased or disabled as a result of service.
5. That no compensation be paid for partial disability to those who are not in need or whose earning capacity is not materially impaired or who earn more than $1,500 a year.
6. That medical opinion decide whether disabilities are caused or favored by military service and that the type of service be considered in arriving at decisions.
7. That the operation of the Emergency Officers' Retirement Act be studied and revised to prevent existing abuses.
8. That in the formulation of future plans, Congress and the Veterans' Administration avail themselves of advice of medical organizations.
9. That civil service regulations that grant undue preference to ex-soldiers be rescinded because of the danger to the efficient conduct of the medical and public health services of the government.

The report pointed out, among other things, that a larger percentage of former medical officers are receiving pensions than other ex-officers, although some of them hold full time government positions.

## OKLAHOMA

**State Medical Meeting and Election.**—The fortieth annual session of the Oklahoma State Medical Association was held in Tulsa, May 24-26, under the presidency of Dr. Henry C. Weber, Bartlesville. Among guest speakers were Drs. Frank C. Neff, Kansas City, "Active Immunization Against Diphtheria"; Walter E. Sistrunk, Jr., Dallas, Texas, "The Gallbladder"; Arthur E. Hertzler, Halstead, Kan., "Indications for Operations for Minor Gynecological Disease"; Marcus O. Shivers, Colorado Springs, Colo., "Thyroid Problems"; Frank D. Dickson, Kansas City, "Low Back Pain with Particular Reference to the Congenital Abnormalities in the Lumbosacral Region," and James W. Hendrick, Amarillo, Texas, "Causation and Treatment of Simple Goiter." Dr. Hugh S. Cumming, Washington, D. C., addressed a general meeting, Wednesday, May 25. Dr. Tracey H. McCarley, McAlester, was named president-elect and Dr. Robert M. Anderson, Shawnee, was installed as president. The next annual session will be held in Oklahoma City.

## PENNSYLVANIA

**Society News.**—The program of the Dauphin County Medical Society, Harrisburg, June 7, included the following speakers, all of Harrisburg: Drs. William K. McBride, "Technic of the Complete Periodic Health Examination"; John A. Daugherty, "Insulin—A Historic Review"; Walter D. Hawkins, "Modern Conception of the Treatment of Diabetes"; Herbert F. Gross, "Surgical Treatment of Diabetes."——Dr. Walter F. Donaldson, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, June 2, on "Business Aspects of Medicine."

### Philadelphia

**Personal.**—Dr. Jacob D. Leebron has been appointed pediatrist to the Northern Liberties Hospital. His service will include a department for the prevention of diseases in children.——Dr. Frederick S. Baldi, medical director of county prisons since January, 1930, has been appointed superintendent and will now hold both positions. He has been acting superintendent since February.

**Fund in Memory of Dr. Deaver.**—The Aid Association of the Philadelphia County Medical Society is establishing a special perpetual fund in honor of the late Dr. John B. Deaver, the income from which will be used to afford aid to needy physicians and their families. Dr. Francis Heed Adler, 313 South Seventeenth Street, Philadelphia, is secretary of the fund, in which all friends of Dr. Deaver are invited to participate.

**Society News.**—A symposium on complications of surgery of the nose and throat was held at the meeting of the Philadelphia County Medical Society, June 8. Drs. Frank Embery discussed "Complications Associated with Intranasal Surgery"; Benjamin D. Parish, "Lung·Abscesses as a Complication Following Tonsillectomy," and John Loftus, "Complications of

Mastoidectomy."——Dr. May G. Wilson, New York, addressed the Philadelphia Pediatric Society, May 10, on "Natural History of Rheumatic Fever in Its Relation to the Evaluation of Therapeutic Measures."——Dr. Arthur W. Proetz, St. Louis, addressed the Philadelphia Laryngological Society, May 26, on "The Displacement Method of Sinus Diagnosis and Treatment."——Drs. Leon Herman and Joseph C. Birdsall addressed the Philadelphia Urological Society, May 23, on "Intermittent Hydronephrosis" and "Present Status of the Disposal of the Ureters in Carcinoma of the Bladder," respectively.

## SOUTH DAKOTA

**State Medical Meeting at Watertown.**—The fifty-first annual meeting of the South Dakota State Medical Association will be held in Watertown, June 20-22, under the presidency of Dr. Willard Allen Bates, Aberdeen. The house of delegates will meet Monday afternoon, June 20, and the scientific sessions will occupy the other two days. Tuesday morning Dr. William W. Duke, Kansas City, will hold a medical clinic and Dr. Harry M. Richter, Chicago, a surgical clinic. Wednesday morning Dr. Charles W. Pollard, Omaha, will conduct a gynecological clinic and Dr. John E. Gonce, Jr., Madison, Wis., a pediatric clinic. Guest speakers include Drs. Duke, on "The Dawn of a Specialty in Medicine—Allergy"; Richter, "Surgical Treatment of Peptic Ulcer"; Pollard, "Obstetrics"; Gonce, "Infantile Paralysis—Diagnosis and Treatment" and Leo G. Rigler, Minneapolis, "Roentgen Diagnosis in Preventive Medicine." The association dinner will be held Tuesday evening, June 21. The South Dakota Academy of Ophthalmology and Otolaryngology will hold its annual meeting, June 21, with the following speakers: Drs. Kenneth A. Phelps, Minneapolis, "Experiences in Bronchoscopy"; Joseph G. Parsons, Crookston, Minn., "Local Anesthesia"; Frederick H. Roost, Sioux City, Iowa, "Incidence of Focal Infection in Acute Sinus Diseases and Treatment" and Clarence E. Robbins, Pierre, "Acute Mastoiditis of the Hemolytic Streptococcic Type."

## TENNESSEE

**Society News.**—The forty-first annual meeting of the West Tennessee Medical and Surgical Association was held at Jackson, May 26-27. Among speakers were Drs. Willis C. Campbell, Memphis, on "Fractures About the Neck of the Femur"; Paul D. Jones, Milan, "Bacterial Heart Disease"; William I. Howell, Lexington, "Treatment of Sepsis by Stimulating Leukocytosis"; Edwin W. Cocke, Bolivar, "Constitutional Psychopathic Personality in Relation to Present-Day Crime and Delinquency," and William O. Floyd, Nashville, "Differential Diagnosis and Surgical Management of Hyperthyroidism."——Dr. Samuel R. Skillern, Jr., Philadelphia, addressed the Chattanooga and Hamilton County Medical Society, Chattanooga, May 12, on frontal sinus operations. Dr. E. Dunbar Newell, Chattanooga, spoke, June 2, on diagnosis and treatment of brain trauma.——At the meeting of the Gibson County Medical Society, Trenton, May 14, speakers were Drs. Oval N. Bryan, Nashville, "General Medicine"; Jennings C. Litzenberg, Minneapolis, "Management of Complications in Labor," and David R. Pickens, Nashville, "Diseases of the Rectum." Drs. Drew W. Luten and Theodore C. Hempelmann, St. Louis, spoke, May 30, on "Diagnosis in General Practice" and "Nose and Throat Infections of Children," respectively.——Dr. Frank H. Norman, Waynesboro, among others, addressed the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society, April 26, on "Modern Methods of Treatment of Angina Pectoris."

## WYOMING

**Health Officers Meet.**—Dr. John H. Goodnough, Rock Springs, was elected president of the Wyoming association of county health officers at the annual meeting in Casper, May 5. Other officers are Drs. Maurice J. Goldberg, Kemmerer, and Victor A. Mokler, Thermopolis, vice presidents, and Walter H. Hassed, Cheyenne, state health officer, secretary. Among the speakers were Drs. William O. McDermott, Casper, on city health administration, and Nathan E. Wells, Newcastle, control of typhoid.

## GENERAL

**Ophthalmic Social Service Workers.**—The National Society for the Prevention of Blindness announces that it will sponsor two courses for medical social workers in eye hospitals and clinics next fall in cooperation with Washington University, St. Louis, and the Massachusetts Eye and Ear rmary, Boston. Social workers interested in this special- training should communicate with the Secretary, National Society for the Prevention of Blindness, 450 Seventh Avenue, New York.

**Reregistration Under the Harrison Narcotic Act.**—Physicians registered under the Harrison Narcotic Act must reregister on or before July 1. Each such physician must register with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to register within the time allowed by law makes a physician liable to a fine or to imprisonment, or to both, and compels him to pay a penalty of 25 per cent on his annual tax when he does register.

**Special Courses in Vienna.**—The eleventh series of intensive European summer courses will be given in Vienna, July 8-August 19, inclusive, under the direction of Dr. George W. MacKenzie, Philadelphia. Courses announced for this year are in ophthalmology and otolaryngology, as in the past ten years, and the second course in surgery, gynecology and obstetrics. Each will provide about 300 hours of instruction, and 50 additional hours will be given on the boat trips to and from Europe. Instruction will be given by Vienna teachers. Each course covers every phase of the subject, with opportunity for practical exercises. Details may be obtained from Dr. MacKenzie, 1724 Spruce Street, Philadelphia.

**Appeal for Aid for Biochemist's Family.**—An appeal to American biochemists for funds to relieve dire financial need of the daughters of the late Johann Ludwig Thudichum, German biochemist and physician, has been extended to the medical profession and workers in related fields. A committee composed of Dr. David L. Drabkin, Philadelphia, and Russell H. Chittenden, Ph.D., and Lafayette B. Mendel, Ph.D., New Haven, Conn., is circulating a memorandum asking for contributions and will transmit the collected fund to the family. Thudichum made important contributions in the field of lipoid chemistry and was a pioneer investigator of pigments. Checks may be mailed to Dr. Drabkin, Medical School of the University of Pennsylvania, Philadelphia.

**Medical Bills in Congress.**—*Changes in Status:* H. Res. 235 has passed the House, authorizing the appointment of a committee composed of five members of the House of Representatives, to investigate government competition with private enterprise. H. R. 11267 has been reported to the Senate, with amendments (S. Rep. 756). This bill, providing appropriations for the legislative branch of the government and effectuating economies in the administration of the federal government, proposes, among other things: (1) to reduce the federal contributions for vocational education during the fiscal year ending June 30, 1933; (2) that, among other things, disabled emergency officers shall not be entitled to retirement under the Disabled Emergency Officers Retirement Act for disabilities *presumptively* of service origin; (3) that, with certain exceptions, veterans of the World War shall not be entitled to hospitalization for non-service disabilities if their incomes are $1,500 or over a year, if single, or $3,500 or over a year, if married. S. Res. 219 has been agreed to, directing the United States Tariff Commission to investigate the differences in the cost of production between the domestic article or articles and the competitive foreign article or articles on the following items: optical instruments and certain other scientific and laboratory apparatus and instruments. S. 276 has passed the Senate, authorizing the construction and equipment of a hospital on the Crow Indian Reservation, Montana. S. 572 providing for "federal cooperation" with the several states in promoting the welfare and hygiene of mothers and children was reached on the Senate calendar June 1, but consideration of the bill was prevented by Senator King, Utah. S. 2987 has passed the Senate authorizing the construction and equipment of a hospital on the Black Feet Indian Reservation, Montana.

## CORRECTION

**Encephalography Under Narcosis Produced by Nonvolatile Anesthetics.**—In the article by Drs. Solomon and Epstein in The Journal, May 21, the amount of morphine sulphate mentioned at the foot of page 1795, first column, should have been 0.016 Gm.

**Medical Examinations in Kansas.**—In The Journal of April 23, a statement was made that six states, including Kansas, must offer the easiest examinations since these states had had no failures for five years. Dr. C. H. Ewing, secretary of the State Board of Medical Registration and Examination in Kansas, writes that Kansas does not permit members of any cults to take examinations of the medical board and that no applicant is permitted to take the examination who is not a graduate of a class A medical school. Hence there have been no failures.

### Raw Milk in the Prevention of Dental Caries

The work of Mrs. Mellanby appears to show that administration of vitamin D to children living under urban conditions diminishes the incidence of caries in teeth already formed (THE JOURNAL, Nov. 21, 1931, p. 1548; April 9, 1932, p. 1313). She has recently published evidence to show that if the diet is cereal free as well as rich in vitamin D the results are still better. But Mr. Evelyn Sprawson, director of dental studies at the London Hospital Dental School, has a somewhat different view. Before the Royal Society of Medicine he introduced evidence that raw milk, whether such as nature provides for the purpose or that of cows, has a profound influence on the development and calcification of the teeth of man and confers some immunity from caries. Since 1908 he has had under dental supervision hundreds of children in institutions. Before admission they did not receive as a rule proper care, principally on account of poverty. They showed a high percentage of dental caries. Thus in one institution there were in 1910 some 1,100 girls and 750 boys of ages ranging from 3 to 16 years. Of the girls, 78 per cent had dental caries, and 148 first permanent molars in 400 were carious at the ages of 10, 11 and 12 taken together. For the boys the figures were 86 per cent and 183 carious molars. From 1925 onward, the boys had a daily ration of a pint of raw milk (milk at no time heated to more than a few degrees above body temperature). Mr. Sprawson did not know of this, but in 1928 and increasingly afterwards he noticed a change in his work—a remarkable diminution in the number of children returning for further treatment after dental caries had once been treated. At first this was attributed to vitamin D, which exists in small amounts in milk, but experience at another institution where cod liver oil with its large content of vitamin D was freely used did not confirm the conclusion. At this institution the milk was delivered pasteurized. It might be thought that a high degree of calcification of the enamel, such as is said to be produced by vitamin D, would protect against dental caries, but Mr. Sprawson finds that this is not so. In Malay, 49 per cent of Chinese coolies, who work stripped to the waist exposed to the powerful sun, have caries. Similar observations have been made in South Africa. Mr. Sprawson therefore concluded that such a balance of vitamin content as is in raw milk, in conjunction with the calcium (which may be in a particularly suitable form) might be the cause of the diminution of children returning. A high percentage of the incidence of caries occurs in those deciduous and permanent teeth the enamel of which is actively laid down, and in some cases fully calcified, during the first four or five years of life, so that a supply of suitable calcium salts and vitamin balance efficiency should be available at that period. Moreover, the incidence of caries is generally progressively less in the teeth, deciduous and permanent, in the order of their eruption, and it is during the earliest portion of this period that "hand feeding" and a faulty diet are most common. This led to an inquiry concerning the effect of a daily ration of raw milk begun during the first twelve months of life. That age was selected because few children are now breast fed. Moreover, it is a period previous to the eruption of the deciduous molars, in which the incidence of caries is high, and also a period when the first permanent molars are forming, in which the incidence of caries is highest. In children who began to take raw milk at later ages, a protective influence on the teeth subsequently erupted was found. Historically, those peoples showing the smallest incidences of caries are found to be those primitive races who nursed their children for the longest periods; i. e., fed them on raw milk.

Mr. Sprawson suggests that boiling or pasteurizing milk alters part of the vitamin content, so as to render enamel less resistant to caries. Whenever a child is hand fed, unless raw milk is given, there is necessarily an unnatural balance of vitamins and possibly other elements in its food. If raw milk forms part of the diet from birth, so long as it is continued all enamel formed has some immunity to dental caries. If it is not begun until later, erupted but incompletely formed teeth may be similarly altered, though in lesser degree. It is problematic whether fully formed teeth can be influenced. If raw milk is not begun till the third or fourth year, protection is not afforded to the deciduous teeth but to the permanent teeth. The converse is also true. If raw milk is taken for only two and one-half or three years after birth, the deciduous teeth are protected, but little if any protection is afforded to the permanent teeth. For ideal dental development in man, Mr. Sprawson holds that raw milk should form part of the daily food till the age of 14 years, but because of the danger of tuberculosis the milk should be from tuberculin-tested cattle.

### "Ambulance Chasing"

Lawyers of a discreditable type have touts on the watch for road accidents, who follow ambulances with injured persons into hospital wards with the object of getting them to sign a contract whereby the lawyer will take proceedings and a share in any damages awarded. Among other evils this system provokes unnecessary litigation. The evil is so widespread that it has earned the name of "ambulance chasing" and the injured person loses to the lawyer a big proportion of his damages. One hospital (the Folkestone) has had a conference with the Law Society on the subject and has amended its rules, so that no lawyer or his representative will be allowed to enter the wards unless the visit is made at the express request of the patient.

### Advances in the Study of Vitamins

It has been shown that vitamins can be produced by irradiation of substances termed provitamins—thus, vitamin D from ergosterol. At the Laboratory of Physical Chemistry, Cambridge, work has been done by Drs. F. P. Bowden and C. P. Snow, which shows that vitamins as well as provitamins are affected by light and can be destroyed by it if a certain wavelength is used. By means of an instrument resembling a spectroscope, intense rays of a certain wavelength were concentrated on a vitamin or provitamin contained in a tiny cell and the sensitiveness of the substance was studied. The provitamin A, carotene, absorbs visible light but is not altered by it. But ultraviolet rays convert it into a substance giving the spectrum of vitamin A and also the chemical reactions of that substance. Biologic tests demonstrating that vitamin A is actually formed will require some weeks for completion. The new substance absorbs waves of a length different from those which the provitamin absorbs and is destroyed by them. This discovery is of practical importance, for it shows that in the manufacture of vitamins only those which the provitamin absorbs should be used, and destruction of the vitamin so formed should be avoided by excluding the rays which it absorbs.

Vitamin B (which protects against beriberi) is quickly destroyed by rays which it absorbs. The isolation of a crystalline substance, hexuronic acid, from lemons, of which small doses are protective against scurvy, has suggested that this is vitamin C. Vitamin D has been produced by irradiation of the provitamin ergosterol. A method preventing destruction of this vitamin by the rays which it absorbs has been suggested. The study of vitamins by precise physicochemical methods is still in its infancy, but it is already clear that it may displace experiments on animals in estimating their amount in a diet and, further, that deficiency in a given vitamin may be made good more easily by a process of selective irradiation than by any other method.

### Investigation of "Cures" for Cancer

The Cancer Hospital, London, undertakes what is not done by any other hospital in the country. It investigates the new "cures" for cancer, which are vaunted from time to time. Every year it receives numerous suggestions for the treatment of malignant disease and requests to try them. In many cases the composition of the preparation was not revealed, and if this is withheld the committee of the hospital always feels compelled to refuse to pursue the matter. Whenever the nature of the composition of the proposed remedy is stated the matter is given careful consideration and, if it appears reasonable, investigation is made. At the annual meeting it was stated that during the year extensive inquiry had been carried out on these lines, but nothing encouraging had resulted, however, one communication had opened a new line of research, which was being actively followed. Mr. R. H. Jocelyn Swan, senior surgeon, said that during the last three years radium had been used in 700 cases in the hospital. Some of the results were astonishing. If cases could only be obtained in the early stage, the statistics, good as they were, would be much better.

### Splitting the Atom

Lord Rutherford has described in the press "a discovery of great scientific importance," the result of experiments carried out by two young men in the Cavendish Laboratory, Cambridge, over which he presides. These men—Dr. J. D. Cockroft and Dr. E. T. S. Walton—are now described as having succeeded in splitting the atom. Lord Rutherford says that it is difficult to say to what the discovery might lead. It could not be claimed that the discovery meant that we should be able to produce an immense amount of electrical energy for commercial purposes, as had been stated, for the simple reason that for every particle of additional energy they got it required millions of particles to make it effective. Cockroft and Walton split the atom by means of a vacuum tube through which millions of particles a second were fired at a speed of 10,000 kilometers a second. The atom has been split before, but in these experiments energies were procured from atoms as they broke up 100 times greater than that of the particles with which they were attacked (with a voltage of 120,000).

### The Control of Pharmaceutic Advertisements

Prof. Marcel Labbé recently brought before the Academy of Medicine a question of great importance. He read a number of advertising leaflets vaunting the merits of a product with a sorbite base, presented to the public as a sugar that has been deprived of all harmful effects for diabetics, whereas, according to Professor Labbé, sorbite is no better tolerated by patients than other carbohydrates. He demands, therefore, that the academy take the initiative in putting the public on its guard against these erroneous statements so harmful to public health, and take a firm stand against the selling with impunity of products likely to be dangerous. French laws are silent on this subject. There is absolutely no control of the value of products advertised to the public, except for serums and vaccines. The law demands only that the exact composition of the product be stated on the label. However, most manufacturers circumvent the law by placing the label on the bottom of the bottle and by printing the technical names in exceedingly small type and with the terms of chemical nomenclature, which are understood only by the initiated. As to the statements in the prospectuses concerning the curative effects of the product, they are formulated with absolute freedom and without any guaranty. It is evident that a system of control would be valuable in the interest of public health; but it is equally evident that the introduction of such a system would cause great confusion in the ranks of the pharmaceutic industry. Nevertheless, the Academy of Medicine has appointed a commission to study carefully the situation and furnish a report on the subject.

### Vocational Guidance

The medical examination of children with a view to determining whether their physical condition reveals any contraindication to the trade or profession that they wish to take up is tending to become more general in France. Such an examination is now required of all students in schools of technical instruction, but it is optional in other schools. Many families are beginning to recognize the usefulness of such examinations and are voluntarily subjecting their children to such tests. The results obtained have led to interesting observations and made a great impression on the public. For example, at Nantes, 1,109 children were examined in 1931, as against 936 children in 1930. These examinations entail a search for three kinds of contraindications for the occupation chosen: medical, educational and economic. As to a group comprising 123 boys and 23 girls, formal contraindications were found in 38 per cent—in 15 per cent for medical reasons. Disorders of vision were discovered that both parents and children did not know existed. The eye examinations revealed, furthermore, that sixty-three young persons did not have normal vision. The medical examiners discovered eleven cases of pulmonary tuberculosis. Five of these children suffering from active tuberculosis were sent to sanatoriums or to the country. The dental examination showed that the parents are not paying sufficient attention to the teeth of their children. Three abnormal children were directed to special centers. Five boys were operated on, before they entered on their apprenticeship, for undescended testis. Three young women were advised not to take up dressmaking, and two boys were cautioned against the textile trade owing to hyperhidrosis of the hands.

### Use of Microscopic Preparations in Decorative Art

Modern decorative art is constantly seeking new designs for tapestries, wallpaper and ladies' dress goods. The imagination of decorative artists has been strained to the uttermost in the attempt to supply new designs. The infinite variety of designs displayed in the veins of marble and other building stones has been frequently studied and imitated; but the images supplied by nature on examination of microscopic preparations have never been utilized. Madame Albin Guillot, widow of a manufacturer of orthopedic apparatus, who is well versed in microscopy and who is also an expert photographer, had the ingenious idea of deriving original decorative motifs from these images. Microscopic preparations richly stained by means of various laboratory reagents and photographed with considerable magnification furnished her with some astonishing pictures in which nature combines freely and repeats the same elements in accordance with arrangements constantly renewed. Pathologic tissues, especially neoplasms, furnish images even more curious and interesting than normal tissues. Madame Albin Guillot has published an album of plates of this kind, in which one can see sections of cancer of the prostate, and adenomas of the breast that present designs of charming originality. Manufacturers of textiles have become interested and are making industrial applications that are scoring a great success. Superbly dressed women are wearing dresses the picturesque design of which is patterned, without their knowing it, after the structure of tumors; or they paper the walls of their apartment with paper the design of which is derived from a sarcoma.

### Decline of the Birth Rate in France

The Alliance nationale pour l'accroissement de la population française, in a study that it has just published on the vital statistics of France for 1931, points out that the birth rate fell off sharply toward the close of the year. A comparison of the birth rate for the corresponding quarters of 1930 and 1931 reveals the following differences: first quarter, increase

937; second quarter, decrease 3,537; third quarter, decrease 4,907; fourth quarter, decrease 11,155; for the entire year, decrease 18,662. The number of marriages, furthermore, having diminished by more than 16,000 it is to be feared that the reduction in the number of births may be still greater in 1932. If one notes that, of the 730,000 births in 1931, 55,000 were of children of foreigners, whereas, of the 680,000 deaths, there were only 30,000 deaths of foreigners, it will be seen that the French excess of births over deaths in 1931 was only 25,000. This small excess runs the risk of being transformed, next year, into a permanent deficit unless something energetic is done to promote a better birth rate. Finally, since the number of emigrants in 1931 exceeded the number of immigrants by more than 25,000, the population of France has in reality diminished, the first time that that has happened since the war.

### Congress of Internal Medicine

The Kongress für innere Medizin was held this year in Wiesbaden. In surveying the results of the session, two objectives in contrast with congresses of recent years were sought by the organization committee: accentuation of the clinicomedical point of view in the official papers of the first three days and—with a certain inner connection—the limitation of the number of individual communications to about half the number presented in previous years. The successful accomplishment of the new program was due primarily to the initiative of the chairman, Professor Morawitz of Leipzig, who has been called to Berlin, as the successor of Professor His, to occupy the chair of internal medicine and serve as director of the first Medizinische Universitätsklinik. The first day's session was held in collaboration with the Deutsche pharmakologische Gesellschaft, whose chairman, the pharmacologist Prof. O. Loewi of Graz, pointed out the inner relations and the mutual interests that characterize clinical medicine and pharmacology. The chief topic considered was "The Effects of Autogenous Substances on the Circulation." The discussants were Sir Henry Hallett Dale of London and Prof. Dr. F. Volhard of Frankfort-on-Main. Sir Henry considered the importance of autogenous substances for the regulation of the circulation in the healthy organism. The chemical regulation of the blood stream in the capillaries is not only dependent on the active substances of the hormone-secreting glands—primarily, epinephrine and vasopressin—but also on certain products of normal cell and tissue metabolism. It is a question of chemical substances that, in contrast with the aforementioned hormones, cause vascular dilatations and lowering of blood pressure. The principal representatives of this group are histamine, choline ester, and compounds of the type of adenylic acid.

Professor Volhard, clinician of Frankfort, supplemented Dale's statements by observations on the pathologically changed circulation. He pointed out the importance of the mentioned substances for a number of pathologic manifestations that have usually been considered of nervous origin. The new conception has proved to be fruitful for the theory of infections, the tuberculin test, certain inflammations, so-called angioneurotic disturbances, shock, cerebral hemorrhage, increase of blood pressure, with or without kidney involvement, and other conditions. Volhard's remarks on the various types of high blood pressure were of practical importance for the clinical study of kidney diseases and for the question as to how convulsions of pregnancy arise. Volhard was the first to describe the pathologic syndromes of "white" and "red" kidneys, which are said to be caused by an unknown hypophysin-like substance, which appears to originate in the kidneys. If in the acute stage of kidney disease the high blood pressure has existed too long, a cure is not likely to be effected and a further progression of the disorder is probable. In Germany, and probably also in other countries, numerous attempts have been made to utilize these therapeutic suggestions in a practical way. Whether, as a matter of fact, there is as much practical therapeutic value in the various preparations derived from muscle extract, and otherwise, as in the first period of optimism was assumed, is for future investigators to decide. At least no decisive success in this direction has as yet been reported. Nevertheless, it appears that these preparations may have the power of improving the blood supply of tissues through dilation of the blood vessels and thus exerting a favorable influence on certain severe and painful disorders, such as angina pectoris and Raynaud's gangrene. The certainty based on a therapeutic success that can be repeated at will, which is necessary for the support of a really favorable opinion, is still lacking. Medicine finds itself, from time to time, in a position in which it gains interesting new theoretical insight, with the prospect of tedious and laborious clinical study before the new methods can be used in everyday practice.

On the second day, Prof. L. Brauer of Hamburg-Eppendorf discussed respiratory insufficiency. Brauer and his collaborators, particularly Knipping, were able to develop an ingenious clinical method of research that permits the continuous registration of respiratory rhythm, air volume and the simultaneous passage of oxygen and carbon dioxide through lungs and blood, under normal and pathologic conditions. The disturbances of gas exchange, due to respiratory paralysis of nervous origin, mechanical obstruction of the air breathed, disturbances of air and blood distribution in the lungs, rarefaction of the air at great altitudes, and interruption of the gas exchange in the pulmonary air vesicles (so-called Brauer's pneumonosis), were discussed with considerable detail. One purpose of these researches is to secure, as far as possible, clear and accurate indications and controls for the treatment of pulmonary tuberculosis by means of artificial pneumothorax, in the promotion and development of which Brauer has performed meritorious service. The two following papers took up the practical side of this important subject. Liebermeister of Düren fixed the range of application of bilateral pneumothorax, which was first successfully employed, fifteen years previously, by Professor Ascoli of Palermo. Ascoli was present and took part in the general discussion. The third paper, presented by Professor Jakobaeus of Stockholm, dealt with lung collapse. He directed attention to the part played by atelectases, and to the interpretation of roentgenograms taken of tuberculous patients.

The chief topic on the third day of the congress was involvement of the stone-free biliary passages. Three eminent investigators in as many different fields discussed the subject: Prof. L. Aschoff, pathologic anatomist of Freiburg; Prof. F. Umber, clinician of internal diseases, Berlin, and Prof. V. Schmieden, surgeon of Frankfort-on-Main. Research in this field has made good progress since the publication of the epochmaking investigation of Naunyn, and, in recent years, particularly through the examination of the bile by the use of a sound, and the roentgenologic exhibition of the biliary passages. Also more detailed anatomic studies (more particularly the researches of Aschoff) have furnished new insight into pathologic manifestations. Stone-free involvement of the efferent biliary passages develops, in the presence of some obstacle preventing the outward flow of the bile, through ascending infection with bacteria from the intestine, or through the dissemination of micro-organisms from the circulating blood. The result is swelling of the liver, with generalized jaundice, there being seldom any collection of pus or any shrinking of the liver. The treatment can usually be confined to dietetic, physical and medicamentous remedies, surgical aid being required only in special cases.

The social setting of the congress this year was of a more festive character than usual, owing to the fact that the congress was preceded by an academic festival in honor of the fiftieth anniversary of the founding of the society. In spite of the economic depression, more than 1,000 participants appeared. Professor Morawitz gave an historical survey of the evolution of the congress during the fifty years of its existence. Since Frerichs and E. v. Leyden founded the society, it has always furthered national and international research, supported the progress of internal medicine, and disseminated much valuable knowledge among the physicians. While special congresses serve to advance certain specialties, as, for example, the Gesellschaft für Verdauungs- und Stoffwechselkrankheiten, and the Gesellschaft für Kreislaufforschung, the Gesellschaft für innere Medizin remains the great mother society, which keeps its gaze fixed on internal medicine as a whole. The accomplishments of the society have been recorded in a monograph prepared by the Berlin clinician Georg Klemperer, at the request of the society, in which the author calls attention to the progress that the transactions of the congress brought about by supporting the high aims of the society with respect to the authoritative position, the unity and the independence of internal medicine through the ever increasing familiarization with the advanced ideas of psychology. "The knowledge that man, although the object of natural research, obeys, through his psychic make-up, his own laws, secures for the clinician independence of research and of his medical attitude toward the auxiliary sciences."

## BUDAPEST

*(From Our Regular Correspondent)*

April 10, 1932.

### Goethe as a Philosopher and Scientist

At the medical society, professor Dr. Julius Donath gave a memorial address on Goethe as a philosopher. The number of those who know of Goethe's pioneer work in the natural sciences is few. When he edited in 1791 to 1793 the "Beiträge zur Optik" in two volumes, he thought more highly of this work than of his poetry. He created something lasting in the field of physiologic optics, dealing with the subjective symptoms caused by light rays entering the eye and with the color sense.

The close observation of nature was awakened in Goethe by the books in his father's library. The old Johann Kaspar Goethe, whose legal ambitions were not gratified by the patricians of Frankfort-on-Main, withdrew into private life, having inherited a fortune; but the father demanded of his son that he select a practical career and accordingly he matriculated at the faculty of law of Leipzig University. Here, however, he dealt rather with poetry and the occult sciences, which he so enrapturingly utilized in his Faust, in the colloquy of the latter with Wagner, in his meeting with Mephistopheles and in his visit to the witch kitchen. Afterward he moved to the University of Strasbourg, where the professors were not so severe with their students. Here he ardently attended the lectures on anatomy, visited the clinics and even attended a course in obstetrics. He liked to be in the company of medical students. Here he worked, in collaboration with Lavater, on his book entitled "Physiognomische Studien." In 1776, he published his work entitled "Beiträge über Tierschädel"—Contributions on the Animal Skull. In Jena, he took a demonstration course under Professor Löder on the bones and muscles, and soon he was giving lectures on the human osseous system in a drawing school. To his great rejoicing here he discovered the intermaxillary bone, which carries the incisors. This was long known of in zoology but not in anthropology. It was futile for Goethe to accentuate that these "intermediate bonelets" can be seen in young human skulls, because they soon merge with the surrounding bones; but they can be discerned in adult monkeys. Professor Löder accepted this discovery, but the great anatomists Merck, Sömmering, Camper and Blumenbach could not be convinced. From his discovery Goethe forthwith concluded the common origin of man and animals, and thus he was the forerunner of evolution. Officially, the scientific world accorded him recognition only one year prior to his death, when the Kaiserliche Leopoldino Karolinische Akademie had his original treatise with his drawings printed.

There have always been princes and royal courts that valued poetry, arts and science, but the relation between Goethe and August, Prince of Weimar, is unique. Traveling through Frankfort, the prince wished to get acquained with the poet of Werther. The talented and educated prince invited, in 1775, Goethe, as his first minister. Weimar, the capital of the tiny country of about a hundred square miles, became the gathering place of poets, scientists and artists whom Karl August assembled about himself, thus making of Weimar the intellectual center of Germany.

Among the numerous tasks entrusted to Goethe was the promotion of the Ilmenau mine. He took to this work with great fervor and ambition, and began a thorough study of mineralogy and geology in order to win the confidence of his prince. To this end he sought connection with Jena professors and utilized his frequent visits to Carlsbad to study Bohemia from the point of view of mineralogy and geology. The Carlsbad museum, unfortunately visited by few people, contains the original writings of Goethe.

Goethe was the first to recognize the importance of excavated bones and petrifactions in the determination of the age of rocks and periods of the earth.

Particularly important is his botanical treatise "Versuch die Metamorphose der Pflanzen zu erklären," an experiment to explain the metamorphosis of the plants. He recognized that in flowers the pollen and stamen holders are in a state of retrogression. He disagreed with Linné, who proclaimed the invariableness of the species, whereas he was convinced that the botanic forms were flexible and in a position to accommodate themselves to the various influences of the earth. His achievements in research he imparted to his innermost circle of friends, among whom were Merck, Schiller, Herder and Charlotte von Stein.

In the eighties of the past century the science of embryology, founded by Roux, demonstrated that parts of the organism may became transposed and shifted during its development. Goethe's ideas laid down in these treatises were the forerunners of Roux's achievements, and it is undeniable that he raised purely descriptive zoology and botany to the rank of actual sciences.

The term "struggle for existence" originated with Darwin, but its conception was already sharply circumscribed by Goethe with the following words: "All things that come to exist seek space and want to persist; therefore they crowd out one another and shorten their existence." The cell doctrine and the recognition that animal and plant cells are identical we owe to Schwann (1839) and to Brücke, the Vienna physiologist; Goethe foresaw this, in his following declaration: "The organism is a simple, but always a multiple being; it seems to be one, yet it is a conglomeration of independent living beings."

Shortly before his death, Goethe was accorded a great satisfaction, when, in the summer of 1831, he submitted to Geoffrey de St. Hilaire for the French Academy his work "The Metamorphosis of Plants," which was translated into French by Soret under his own supervision, and Hilaire passed the work with the following report: "When Goethe published his work in 1790, the scientific world did not take very much heed of it; it was even regarded as a lapse. In fact, we had to deal with a slip, but such a one as occurs with genius only."

In his optical studies relating to the spectrum, he was led astray by some idealistic preoccupation. He could not accept that white should be composed of several colors. Goethe was unjust when he jeered at Newton's idea in this matter. Goethe's explanation as to the color phenomena was generally recognized, however. His studies relating to the so-called colored shadows are a treasure even today.

## Marriages

RUSSELL C. CARRELL, Des Moines, Iowa, to Miss Marguerite Cheney, in Chicago, March 15.

LINDLEY V. SPRAGUE, Madison, Wis., to Miss Virginia Clement of Glen Ellyn, Ill., May 8.

RICHARD E. MARTIN, Two Rivers, Wis., to Miss Catherine O'Brien of Milwaukee, May 24.

DEAN K. STINSON, Rochester, Ind., to Miss Elizabeth Alice Whitaker of Detroit, April 9.

HERBERT J. WITTE, Marathon, Iowa, to Miss Eola Friedman of St. Paul, March 15.

## Deaths

**Orlando Henderson Petty** ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1904; member of the House of Delegates of the American Medical Association, 1926-1928; professor of diseases of metabolism, University of Pennsylvania Graduate School of Medicine; member of the American College of Physicians; past president of the Philadelphia County Medical Society; formerly director of the department of public health of Philadelphia and assistant medical inspector in the division of communicable diseases, bureau of health; served during the World War; was awarded the Congressional Medal of Honor, the Distinguished Service Cross, the French Croix de Guerre with Palm and the Italian War Cross; chief of the department of diseases of metabolism, Philadelphia General Hospital; consultant in diseases of metabolism and malnutrition, Shriners' Hospital for Crippled Children; consultant in metabolic disorders, Rush Hospital for Consumptives; author of "Diabetes—Its Treatment by Insulin and Diet"; aged 58; died, June 2, of a self inflicted bullet wound.

**Richard Ward Westbrook,** New Canaan, Conn.; Yale University School of Medicine, New Haven, 1891; fellow of the American College of Surgeons; professor of orthopedic surgery, Long Island College Hospital, Brooklyn, 1902-1906; formerly on the staffs of the Bethany Deaconess Hospital, and St. Mary's Hospital, Brooklyn, and the Brooklyn Hospital; aged 68; died, May 11, of coronary disease.

**John Markley Ross,** Richland Center, Wis.; St. Louis College of Physicians and Surgeons, 1905; member of the State Medical Association of Wisconsin; past president of the Richland County Medical Society; served during the World War; aged 49; died, May 7, in the Richland Hospital, of meningitis following an otitis media and mastoiditis.

**Edward Winfield Howard,** Fairmont, W. Va.; Jefferson Medical College of Philadelphia, 1894; member of the West Virginia State Medical Association; past president of the Marion County Medical Society; formerly on the staffs of the Cook Hospital and the Fairmont No. 3 Hospital; aged 61; died, April 16, of angina pectoris.

**James Henry Carr** ⊕ Buffalo; University of Buffalo School of Medicine, 1900; fellow of the American College of Surgeons; served during the World War; attending surgeon to the Emergency Hospital of the Sisters of Charity and St. Francis Asylum for Aged; aged 63; died, May 21, of abscess of the lung.

**Jesse Edwin Hahn,** Warsaw, Ohio; Medical College of Ohio, Cincinnati, 1901; member of the Ohio State Medical Association; for many years member of the school board; formerly member of the county board of health; aged 61; died, May 4, in the Coshocton (Ohio) City Hospital, of heart disease.

**Thomas Marshall Jones,** Alexandria, Va.; University of Maryland School of Medicine, Baltimore, 1870; member of the Medical Society of Virginia; for many years coroner; aged 83; died, May 11, in the Georgetown University Hospital, Washington, D. C., of hypertrophy of the prostate and uremia.

**Arthur J. Burridge,** Winnipeg, Manit., Canada; Manitoba Medical College, Winnipeg, 1897; associate professor of medicine at his alma mater; fellow of the American College of Physicians; for many years on the honorary attending staff of the Winnipeg General Hospital; aged 56; died, March 15.

**Perry William McLaughlin** ⊕ Norristown, Pa.; Johns Hopkins University School of Medicine, Baltimore, 1907; served during the World War; aged 49; died, May 20, in the Veterans' Administration Hospital, Coatesville, of a self-inflicted wound which severed an artery in his groin.

**Moses A. Karol** ⊕ Decatur, Ill.; Loyola University School of Medicine, Chicago, 1919; served during the World War; on the staffs of the Wabash Employees' Hospital, St. Mary's Hospital, and the Decatur and Macon County Hospital; aged 38; died, April 24, in Chicago, of heart disease.

**Frank Leon Slater** ⊕ Rochester, N. Y.; Syracuse University College of Medicine, 1920; fellow of the American College of Surgeons; on the staffs of the Rochester General Hospital and the Monroe County Hospital; aged 36; died, April 6, of cyanide poisoning, self-administered.

**Anstruther Davidson** ⊕ Los Angeles; University of Glasgow Medical Faculty, Glasgow, Scotland, 1881; professor emeritus of medicine (dermatology) College of Medical Evangelists; for many years on the staff of the Los Angeles General Hospital; aged 72; died, April 3.

**Alexander Brown Kalbaugh** ⊕ Western Port, Md.; University College of Medicine, Richmond, Va., 1907; served during the World War; formerly secretary of the board of health of Western Port; aged 48; died suddenly, May 15, of coronary embolus.

**George John Van Vechten,** Blakely, Pa.; Albany (N. Y.) Medical College, 1891; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 66; died, May 1, in the Mid-Valley Hospital, Peckville, of mastoid infection.

**Thomas Lovell McRitchie,** *Chatham, Ont., Canada;* Western University Faculty of Medicine, London, 1889; health officer of Chatham and coroner of the district; formerly member and chairman of the board of education; aged 69; died, March 19.

**Albert G. Hamilton** ⊕ Thermopolis, Wyo.; Medical College of Ohio, Cincinnati, 1888; fellow of the American College of Surgeons; president of the Hot Springs County Medical Society; manager of the Hopewell Hospital; aged 68; died, April 7.

**William B. Wakefield** ⊕ Peoria, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1907; on the staff of the Methodist Hospital of Central Illinois; aged 47; died, May 11.

**Henry Ernest Beck** ⊕ Moline, Ill.; National Medical University, Chicago, 1906; served during the World War; aged 65; on the staff of the Moline Public Hospital, where he died, May 16, of injuries received in an automobile accident.

**Hobert Le Gear Collins,** New Westminster, B. C., Canada; University of Toronto Faculty of Medicine, 1900; served with the Canadian Army during the World War; aged 51; died, February 26, in the Royal Columbian Hospital.

**Samuel N. Harvey** ⊕ Chicago; Bellevue Hospital Medical College, New York, 1875; aged 79; on the staff of the Illinois Central Hospital, where he died, May 20, of acute hepatitis.

**Edward Eldred Kellogue Chapman,** Defiance, Ohio; Hahnemann Medical College and Hospital, Chicago, 1888; member of the Ohio State Medical Association; on the staff of the Defiance Hospital; aged 73; died, March 26.

**Constant Perkins Wilson, Jr.,** Fort Smith, Ark.; University of Pennsylvania School of Medicine, Philadelphia, 1910; member of the Arkansas Medical Society; served during the World War; aged 49; died, April 1, of pneumonia.

**Charles Daniel Werley** ⊕ Reading, Pa.; Jefferson Medical College of Philadelphia, 1889; secretary and for many years member of the school board of Topton, Pa.; aged 69; died, April 19, of chronic pulmonary tuberculosis.

**W. Oliver McLane,** Frostburg, Md.; University of Maryland School of Medicine, Baltimore, 1892; member of the Medical and Chirurgical Faculty of Maryland; aged 63; was found dead, May 14, of heart disease.

**J. Ernest Brown** ⊕ Lake Providence, La.; Atlanta College of Physicians and Surgeons, 1901; bank president; formerly member of the state board of health; aged 53; died, May 6, of a self-inflicted bullet wound.

**Jasper J. Bland,** Beaumont, Texas; University of Louisiana Medical Department, New Orleans, 1882; formerly chief diagnostician for the state board of health of Louisiana; aged 81; died, March 30, of pneumonia.

**Joseph Vincent Missett** ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1898; for many years on the staff of the Misericordia Hospital; aged 61; died suddenly, May 14, of angina pectoris.

**Silvanus Blanchard Newton,** Chevy Chase, Md.; University of Pennsylvania School of Medicine, Philadelphia, 1894; served during the World War; aged 61; died, April 30, of streptococcus septicemia.

**James Franklin Crump,** Pine Bluff, Ark.; University of Arkansas School of Medicine, Little Rock, 1905; member of the Arkansas Medical Society; aged 58; died, May 6, of cerebral hemorrhage.

**Victor Sulviro Merritt,** Springfield, Mass.; Medico-Chirurgical College of Philadelphia, 1897; member of the Massachusetts Medical Society; aged 69; died, May 2, of coronary thrombosis.

**George De Witt Culver** ⊕ San Francisco; University of California Medical Department, 1903; member of the American Dermatological Association; aged 55; died, May 9, of pernicious anemia.

**William Thomas Jones,** Fort Davis, Texas; University of Georgia Medical Department, Augusta, 1884; aged 79; died, April 26, in Galveston, of hypertensive heart disease and arteriosclerosis.

**Howard Clarence Minor,** Steubenville, Ohio; Ohio Medical University, Columbus, 1897; member of the Ohio State Medical Association; aged 62; died, May 9, in Cleveland, of heart disease.

**Cornell Nathan Smith** ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1905; on the staff of the General Hospital; aged 53; died, April 26, of uremia and hypertensive heart disease.

**Sidney A. Stokes,** Cornersville, Md.; Jefferson Medical College of Philadelphia, 1884; member of the Medical and Chirurgical Faculty of Maryland; aged 69; died, May 19, of heart disease.

**Adrian Peter Van Deinse,** Sayville, N. Y.; Albany Medical College, 1886; aged 70; died, April 24, in a sanatorium at Brentwood, of arteriosclerosis, myocarditis and acute pulmonary edema.

**Horace Bunnell Boyd,** Richmond, Ind.; Starling Medical College, Columbus, Ohio, 1881; member of the Indiana State Medical Association; aged 76; died, May 14, of laryngeal tuberculosis.

**Charles W. Tidball,** Norwood, Ohio; Eclectic Medical Institute, Cincinnati, 1879; aged 75; died, May 6, in the Cincinnati General Hospital, of cerebral hemorrhage and pneumonia.

**Robert Tyre Macdonald,** Cowansville, Que., Canada; McGill University Faculty of Medicine, Montreal, 1881; aged 75; died, February 23, at the home of his son in Montreal.

**Anne Tefft Bingham** ⊕ New York; Syracuse University College of Medicine, 1900; member of the American Psychiatric Association; aged 56; died, May 20, of heart disease.

**George Schoeps,** Paris, France; University of the City of New York Medical Department, 1891; member of the Medical Society of the State of New York; aged 74; died, April 2.

**J. Charles Schlicht,** North McAlester, Okla.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1903; aged 50; died, April 2, of acute septic endocarditis.

**George H. Parshall,** Freeport, N. Y.; Long Island College Hospital, Brooklyn, 1884; formerly member of the state legislature; aged 88; died, April 2, of pulmonary edema.

**William Hugus Keck,** Santa Cruz, Calif.; Western Pennsylvania Medical College, Pittsburgh, 1889; aged 82; died, March 24, of arteriosclerosis, myocarditis and nephritis.

**Arthur William Wheeler** ⊕ Toledo, Ohio; Toledo Medical College, 1902; served during the World War; aged 57; died, May 9, of gangrenous appendicitis and peritonitis.

**John T. Boldrick** ⊕ Lebanon, Ky.; Louisville and Hospital Medical College, 1908; proprietor of the Boldrick Infirmary; aged 47; died, May 6, of cerebral hemorrhage.

**Joseph Francis Higgins** ⊕ Trenton, N. J.; Medico-Chirurgical College of Philadelphia, 1902; aged 55; died, April 23, in a hospital at Philadelphia, of toxic poisoning.

**Godfrey F. Hamlen,** Rochester, Mich.; Michigan College of Medicine and Surgery, Detroit, 1896; aged 66; died, May 5, in the Harper Hospital, Detroit, of diabetes mellitus.

**John Henry Edmison,** Brandon, Manit., Canada; Manitoba Medical College, Winnipeg, 1898; on the staff of the Brandon General Hospital; aged 58; died, March 22.

**James Benono Beckett,** Spiro, Okla.; Memphis (Tenn.) Hospital Medical College, 1903; aged 70; died, March 10, following an operation for hypertrophy of the prostate.

**Ralph Elmer Jenkins** ⊕ Pittsburg, Kan.; Ensworth Medical College, St. Joseph, Mo., 1908; aged 46; died, May 4, in St. Luke's Hospital, Kansas City, of heart disease.

**Joseph Morley Jory,** St. Catharines, Ont., Canada; Trinity Medical College, Toronto, 1894; for many years member of the board of education; aged 64; died, March 21.

**Frank A. Morrison,** Uhrichsville, Ohio; Pulte Medical College, Cincinnati, 1890; aged 72; died, May 5, in the Twin City Hospital, Dennison, of chronic myocarditis.

**Everett Layton Pirkey,** Louisville, Ky.; University of Louisville School of Medicine, 1911; served during the World War; aged 48; died, May 16, of heart disease.

**Eugene B. Appelget,** Chicago; St. Joseph (Mo.) Hospital Medical College, 1880; aged 85; died, May 24, of injuries received when he was struck by an automobile.

**Marcus Clifford Reeves** ⊕ Vidalia, La.; Baltimore University School of Medicine, 1897; aged 57; died, May 4, in Natchez, Miss., of chronic interstitial nephritis.

**Dennis Alexis Myers** ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1902; aged 64; died, March 9, in St. Joseph's Hospital, of influenza and pneumonia.

**John V. Bower,** Indianapolis; Butler University Medical Department, Indianapolis, 1880; aged 81; died, April 28, of chronic myocarditis and interstitial nephritis.

**Frank Merton Robertson Spendlove,** Westmount, Que., Canada; University of Bishop College Faculty of Medicine, Montreal, 1881; aged 77; died, March 22.

**Berkeley Sherwood-Dunn,** Nice, France; Bellevue Hospital Medical College, New York, 1884; served during the World War; aged 64; died, March 29.

**Duncan Hamilton McAllister,** Sussex, N. B., Canada; McGill University Faculty of Medicine, Montreal, Que., 1898; aged 60; died, March 6, of pneumonia.

**Granville Hampton Richards** ⊕ Port Deposit, Md.; University of Maryland School of Medicine, Baltimore, 1908; aged 48; died, May 10, of heart disease.

**Elihu Ashby Fluesmeier,** Wright City, Mo.; University of Missouri School of Medicine, Columbia, 1891; aged 61; died, May 4, of heart disease.

**Charles B. Marks,** Grants Pass, Ore.; Detroit College of Medicine, 1890; veteran of the Spanish-American War; aged 65; died suddenly, March 27.

**Carl J. Schneider,** New York; University of the City of New York Medical Department, 1884; aged 73; died, March 31, of carcinoma of the tongue.

**Samuel Nelson Irwin** ⊕ New York; University of the City of New York Medical Department, 1892; aged 69; died, May 5, of heart disease.

**Henry B. Wright,** Gainesville, Ga.; Meharry Medical College, Nashville, Tenn., 1914; aged 42; died, May 6, of cerebral hemorrhage.

**Wallace Allison Reed** ⊕ Covina, Calif.; University and Bellevue Hospital Medical College, New York, 1913; aged 42; died, March 27.

**Alexander M. Cowden,** Washington, Iowa; College of Physicians and Surgeons, Keokuk, 1880; aged 77; died, April 16, of senility.

**James Walsh,** Mount Stewart, P. E. I.; University of Pennsylvania School of Medicine, Philadelphia, 1877; died, February 26.

**John W. Chamberlain,** Wyalusing, Pa.; Jefferson Medical College of Philadelphia, 1886; aged 72; died, May 1, of myocarditis.

**Ursin Prejean,** Carencro, La.; University of Louisiana Medical Department, New Orleans, 1877; aged 76; died, March 27.

**David Thompson** ⊕ Denver; Denver College of Medicine, 1891; aged 75; died, April 30, in Long Beach, Calif.; of heart disease.

**George E. Munroe** ⊕ New York; College of Physicians and Surgeons in the City of New York, 1877; died, April 3.

**Jason Turner,** Heuvelton, N. Y.; Detroit Homeopathic Medical College, 1873; aged 84; died, April 4, in Ogdensburg.

**Robert Withers Poellnitz,** Medford, Ore.; Kentucky School of Medicine, Louisville, 1908; aged 53; died, March 23.

**Horace Porter Gillingham,** Brooklyn; New York Homeopathic Medical College and Hospital, 1894; died, April 3.

**Joel A. Cooper,** Bryson City, N. C. (licensed, North Carolina, by years of practice); aged 84; died, February 11.

**Jonas Jacobs,** New York; College of Physicians and Surgeons, Baltimore, 1886; aged 69; died, April 1.

## Bureau of Investigation

### ABORTIFACIENT PASTES

### The Exploitation and Dangers of Pastes Sold for Producing Therapeutic Abortion

There are on the European market various pastes that are exploited as simple means of performing therapeutic abortions. The most popular ones are "Interruptin," devised by a Berlin pharmacist, Heiser, and "Provocol," the formula of Dr. J. H. Leunbach, a gynecologist of Copenhagen. The Heiser product appears to be secret in composition. Leunbach has published (*Monatschr. f. Geburtsh. u. Gynäk.* **87**:509, 1931) the formula of his paste, which is given as:

| | | |
|---|---|---|
| Olive oil | 120 | gm. |
| Cacao butter | 10 | gm. |
| Potassium hydroxide | 18 | gm. |
| Sodium hydroxide | 7 | gm. |
| Iodine | 2.5 | gm. |
| Potassium iodide | 7.5 | gm. |
| Tincture of benzoin | 10 | gm. |
| Tincture of myrrh | 5 | gm. |
| Thymol | 0.25 | gm. |
| Distilled water, to make | 250 | gm. |

This paste, known in Europe as Provocol, is now on the American market under the name "Leunbach' Paste." It comes in a collapsible tube with a turn-key and an intra-uterine cannula to be attached to the mouth of the tube.

For the past year or two, physicians in Germany have been urged to employ these pastes as an allegedly simple means of performing therapeutic abortions. It is claimed that the method can readily be used in the physician's office and the patient return to her home immediately and without danger. The instructions to inject the uterine cavity, through the cannula, from 15 to 50 cc. of the paste, the amount injected depending on the duration of the pregnancy. The claim is made that within thirty-six hours after the injection, the uterus generally will empty itself with a moderate amount of bleeding and with little pain, and in a manner that is even smoother than a spontaneous abortion.

The preparation Leunbach' Paste, now on the American market, is put out by the Vauka Chemical Works, Inc., of Newark, N. J. A leaflet sent out by this company has this to say about the product:

> "LEUNBACH' PASTE consists of a soap base in which iodine, potassium iodide, thymol and astringents are incorporated. It is packed in collapsible tubes with turn-key and applied by means of an especially constructed intrauterine metal cannula with a rounded tip.
>
> "LEUNBACH' PASTE is formulated on the principle of producing a continuous action upon the uterine mucous membrane, and in this way bringing about a separation of the ovum. It is indicated in spontaneous abortions with retention of the entire, or parts of the ovum. Its chief indication, however, is the induced arrest of the natural process, for therapeutic reasons. It offers distinct advantages over the usual curettage."

Leunbach in a recent article (*Monatschr. f. Geburtsh. u. Gynäk.* **90**:446, 1932) maintains that in using these pastes it is necessary, in order to avoid danger, that they must be free from air. He also states that as they are not antiseptic enough to guarantee against sepsis, the cervical canal must be free from pathogenic bacteria. Further, they should not be used during the first six weeks of gestation.

It is not surprising, in view of the enthusiastic reports of the manufacturers and advocates of the various pastes of this type, together with the obvious simplicity in their use, that the products have become popular. Foreign medical literature, however, indicates that ideal results from the use of such pastes —that is, spontaneous expulsion of the ovum without much pain or bleeding—are obtainable in only about one-fourth of the cases. In many instances, the uterine contractions are unusually painful, and the period of expulsion may last for five or six days. In others, there is severe hemorrhage and many instances are on record in which the uterus had to be emptied instrumentally or digitally.

Some patients develop fever and, in all cases, there is danger of perforation of the uterus, with the almost inevitable peritonitis. In one case reported by Seitz (*Zentralbl. f. Gynäk.* **56**:885, 1932), peritonitis resulted not from perforation, but from penetration of the infection through the uterine wall to the peritoneum of the culdesac of Douglas.

Within a comparatively short period of time, there have recently appeared in German literature reports of twenty-five deaths that have resulted from the use of these abortifacient pastes. Doubtless, more fatalities have occurred than have been reported. Some of the deaths, according to the reports, were caused by air embolism and others by fat embolism. Kustner (*Zentralbl. f. Gynäk.* **56**:754, 1932) has proved experimentally that in some cases the death was attributable to the poisoning by the paste (Interruptin) itself. Kustner injected into the veins of guinea pigs from 1 to 1.5 cc. of the filtrate of a 1:75 solution of Interruptin, and the animals died within from a few minutes to three hours. As from 30 to 50 cc. of Interruptin is supposed to be injected into the uterine cavity to produce abortion, death might ensue if 1 to 1.5 cc. of the paste finds its way into the general circulation. The paste, Interruptin, is said to quickly liquify in the uterus, because of the body heat, and its entrance into the bloodstream is thus favored, especially if it reaches the placental site.

Naturally, the use of these pastes has a medico-legal significance. It is reported by Brack (*Zentralbl. f. Gynäk.* **56**:687, 1932) that two physicians in Hamburg used Interruptin to produce abortions and both patients died within a few minutes. The judge before whom the physicians were tried was lenient, saying that he did not hold them to blame so much as the blatant advertisements of the manufacturers. He warned, however, that in the future he would deal severely with physicians who used such pastes.

As has already been stated, physicians in this country are now receiving circulars extolling the alleged virtues of Leunbach' Paste. These describe how readily the paste may be used to produce abortions for therapeutic purposes. It does not take much stretch of the imagination to believe that physicians and midwives who make a business of performing abortions illegally will turn to such pastes, because of their simplicity. It is not inconceivable that some reputable physicians, now in dire financial straits, may be tempted to use this simple means for inducing abortion when the therapeutic indications are not clear.

In the matter already quoted from the Vauka Chemical Works' circular on Leunbach' Paste, it will be noted that the physician is told that the paste is "indicated in spontaneous abortions with retention of the entire, or parts, of the ovum." Such a statement may easily lead to fatalities, because as Wagner has pointed out (*Monatschr. f. Geburtsh. u. Gynäk.* **90**:445, 1932), such pastes are most dangerous when used in cases where an abortion is in progress and bleeding is taking place. In these cases, the paste might easily be injected into open veins in the placental site and lead to paste embolism or to fatal poisoning.

### INFLUENCE OF HEREDITY ON CANCER

*To the Editor:*—Referring to your editorial on the influence of heredity on cancer (THE JOURNAL, May 7), may I call attention to a neglected method for determining the importance of hereditary factors in the etiology of cancer and other tumor formations. I have in mind the method based on the study of twins.

As all know, twins are of two kinds, monozygotic and dizygotic. Monozygotic twins have the same hereditary endowment, whereas dizygotic twins, like siblings, do not have an identical heredity, although they are the offspring of the same parents.

If cancer occurs on the basis of heredity as an essential etiologic factor, then in cases of monozygotic twins, if one is affected, the other will be likely to be similarly affected, even as regards the type of growth and its localization. In cases of dizygotic twins, the chance is greatly against such correspondence.

It would be a simple matter for any of the cancer research foundations or large clinics to investigate cases of cancer in twins and to derive from a comparison of monozygotic and dizygotic twins a measure of the importance of heredity in the etiology of cancer.

The literature contains, here and there, reports of such cases, but in order to settle the issue it will be necessary to collect at least one hundred pairs of twins with cancer. In other words, there must be an amount of this type of material that would be sufficient for statistical treatment.

About two years ago I undertook a research of mental disorders in twins for a similar purpose. In the course of the study I came across a case of a pair of monozygotic twins born in 1849. Both twins had had attacks of manic-depressive psychoses, for which they were treated in state hospitals in Pennsylvania. It so happens that they both eventually died within a few months of each other of carcinoma of the right side of the face.

This case was referred to me by Dr. S. M. Miller, superintendent of the Norristown State Hospital, Norristown, Pa.

Aaron J. Rosanoff, M.D., Los Angeles.

Comment.—The occurrence of cancer in identical twins is of great significance. Unfortunately, such an occurrence is so rare that it has not been possible to secure enough cases to give important results. Up to the present, only about half a dozen such cases have been described in the medical literature of the entire world. Therefore, it is improbable that it would be possible to collect anything like the hundred pairs of twins with cancer desired for statistical study. A serious difficulty in interpreting the significance of the few cases already recorded in which identical twins have developed identical tumors lies in the fact that no one seems to have thought it important to report the equally significant occurrence of cancer in one of a pair of identical twins and its absence in the other.—Ed.

## PUBLIC HEALTH INTELLIGENCE OF THE HEALTH ORGANIZATION OF THE LEAGUE OF NATIONS

*To the Editor.*—May I through the courtesy of your columns bring to the notice of public health administrators the facilities that exist in the Health Organization of the League of Nations for the supply of information relating to the detailed application of different public health methods in various countries. In addition, comparative information is available with regard to epidemiologic statistics and public health legislation.

The Health Organization is willing to supply, as far as possible, data on these branches of preventive medicine.

Inquiries are, however, limited to those from the heads of large administrations or the heads of scientific institutions, who should indicate the purpose for which the information is required in view of the amount of work that unconsidered requests necessarily involve. Furthermore, inquiries should be limited to information that is not already in the medical press.

All inquiries should be addressed to the Medical Director, Health Section, marked "Public Health Intelligence," League of Nations, Geneva, Switzerland.

Ludwik Rajchman, Geneva.
Medical Director, Health Section,
League of Nations.

## "TREATMENT OF HEMOPHILIA BY AN OVARIAN EXTRACT BY BIRCH'S METHOD"

*To the Editor.*—Female sex hormone therapy in hemophilia seems to be proving of distinct value. Too great care, therefore, cannot be exercised in scrutinizing all reports of this treatment of hemophilia before permitting their publication.

A case in point is the report by Drs. Alvin G. Foord and Ben R. Dysart in The Journal, April 23. They here reported the stoppage of bleeding by an injection of ovarian extract, the hemorrhage ceasing within five minutes of the injection. No one familiar with this therapy would expect or credit an effect of the ovarian extract within five minutes of its administration. The bleeding recorded in the patient's family is quite inadequate to establish a diagnosis of hemophilia.

I have closely observed the use of ovarian extract therapy on several severely hemophilic patients by Dr. Charlotte Wiedemer of Cincinnati during the past year. The treatment has definite value, although it is by no means entirely corrective for the hemophilic condition. The effect of a single injection is slight, full benefit coming only after injections have been given every two or three days for a week or more.

C. A. Mills, M.D., Cincinnati.
Professor of Experimental Medicine,
University of Cincinnati College
of Medicine.

### IMPOTENCE

*To the Editor:*—Recently a single man, aged 24, came to me for medical advice, as for the past two and a half years he has been unable to have an erection. In discussing the condition with this patient, he tells me he has never had intercourse more than once monthly, and that while he has masturbated to some extent he feels that he has done no more of it than is indulged in by the average individual. A complete physical examination reveals nothing abnormal other than the symptoms mentioned, except that the hearing is slightly deficient. I am at a loss as to what should be done. Can you outline a course of treatment that might enable me to be of service to him? I may say here that this man is of keener intelligence than the average individual. Please omit name and city.

M.D., Mississippi.

Answer.—From the history, it may be assumed that the presence of syphilis, diabetes and cerebrospinal conditions have been ruled out. It is also evident that the masturbation is not the cause of the impotence.

The history does not give clear information as to whether the inability to have an erection is of recent origin or whether it has existed from the commencement of the patient's sexual life. This is important as regards prognosis, as a patient who was at one time normal in this regard is almost certain to get well with proper treatments, while those who have always been weak sexually, showing that there might possibly exist a congenital weakness of all the sexual centers, give a rather doubtful prognosis. However, the fact that the patient has indulged in masturbation makes the prognosis better, as it indicates that the patient has sexual feelings. It is also important to establish whether the patient could obtain an erection during masturbation, as this would also indicate that there is no gross organic deficiency in the sexual apparatus to prevent an erection.

The main point in all cases of impotence is accurate diagnosis. It must be definitely established by a competent specialist whether there exists any local congestion in the prostate or prostatic urethra. The former can be determined by an examination of the prostate by rectum, and the latter by inspecting the prostatic urethra with the cysto-urethroscope, always remembering that it is not necessary to find gross pathologic changes by this examination, but that a mere congestion may be sufficient to cause all the symptoms.

If such local congestions are found, it is of the utmost importance to remove them before starting any stimulating treatment. In this case the patient should be treated every five or six days by gentle massage of the prostate and instillations of weak silver nitrate solution with the Bangs sound syringe. The first solution employed should be 1:3,000, and this strength may gradually be increased until a strength of 1:500 is reached. During this preliminary treatment, the patient must avoid tea, coffee, alcoholic liquors and all sexual excitements, especially ungratified sexual excitements.

Many patients become absolutely well as soon as the local congestions have been removed. Others, however, especially if the condition has lasted for a long time, may need stimulating treatment, as there has developed a weakening of the muscles involved in the act of connection.

The following stimulating treatment may be employed not only in the cases just mentioned but also in those cases in which there is no local congestion but a weakened condition of the sexual muscles.

The stimulating treatment consists in the use of the sinusoidal-faradic current of moderate rapidity and as strong as the patient can bear without any pain. It is important that no pain be caused and that the patient be informed of this fact, as some patients will believe that the more of the electricity they get, the better, and will therefore allow themselves to receive strong currents without a murmur, which is harmful. One cable is connected with a rectal electrode and the other with a wet-sponge electrode applied to the perineum and the current is allowed to pass for about ten minutes. Treatments may be given every third or fourth day.

At present there is no aphrodisiac, whether made from a testicular extract or otherwise, that has any beneficial effect in these cases. Whatever good results have been reported were either accidental or psychic.

The vast majority of cases will respond favorably to the treatment outlined, but occasionally cases are seen in which there is a definite psychic inhibition, such as fear of pregnancy, fear of venereal disease or fear of being discovered in the act. Such persons must receive common sense general treatment, but, while admitting the possibility of a psychic impotence, the physician must not make the mistake so often made of considering every case of impotence psychic and as a result neglect to submit the patient to a thorough examination for organic conditions.

## TREATMENT OF SYPHILIS

*To the Editor:*—Will you kindly advise me whether an individual who has received intensive antisyphilitic treatment, consisting of 145 neoarsphenamine and bismuth injections for one year and in whom no change in the original 4+ Wassermann reaction has materialized, should receive further treatment and, if so, for how long a time, if the Wassermann reaction remains constantly positive without any variation? The spinal fluid is positive. Kindly omit name. M.D., New York.

ANSWER.—After a year of such strenuous treatment, a rest is indicated and a thorough neurologic examination before further treatment can be planned. If there is a trend toward dementia paralytica and no contraindications to tryparsamide are found, a course of this drug alternating with mercury should be given. If the nervous involvement is of some other type, after a rest of at least two months less strenuous therapy with alternation of one of the arsphenamines and mercury may be resumed, iodides being given before the course of arsphenamine and during the administration of mercury. The blood reactions should be regularly noted and an examination of the spinal fluid should be made once a year. The general good health of the patient is the first desideratum. If a second year of treatment shows but slight improvement, some form of fever therapy may be used. This patient should have some treatment as long as he lives, though it may be but one course a year. It is often advisable, however, not to discourage him by telling him this.

## COMPENSATION FOR LOSS OF VISION

*To the Editor:*—May I ask a question concerning the interpretation of the standard method approved by the House of Delegates at the session of the American Medical Association in Atlantic City in 1925, in determining impairments to the vision of a patient who has a corneal opacity near the periphery of the pupil? This corneal opacity casts a shadow on the visual field and produces some shadowing near the periphery when the field is taken by the usual perimetric methods. Has it been the intention of the committee in estimating visual impairments to include this as a disturbance of the field of vision, or have visual field disturbances reference only to actual pathologic changes in the field, such as constriction of the field due to disease of the optic nerve, or the results of acute retinitis and other pathologic conditions of the retina? In interpreting corneal opacities our industrial commission is insisting that, in addition to the reduction of visual acuity which results, a visual field factor be applied as well. Could you advise me what the intention of the committee was with reference to such corneal opacities?

HARRY WINKLER, M.D., Charlotte, N. C.

ANSWER.—It was not the intention of the committee to include visual field defects due to opacities of the cornea. If the opacity is sufficiently central to cause an interference with the visual acuity the compensation would be adequate to care for the damage done. But if the opacity is eccentric to the pupillary area, it is questionable whether a "shadow on the visual field" could be estimated with sufficient accuracy for purposes of compensation. Furthermore, on page 9 of the compensation report the second paragraph states that "compensation for loss in industrial visual efficiency as provided for above does not include compensation for any cosmetic defect. . . . Additional compensation should be awarded for such losses when not specifically provided for by statute." Consequently, it would seem to the committee that such corneal opacity should be compensated for on the basis of a cosmetic defect rather than a "shadow on the visual field."

## ADMINISTRATION OF ARSPHENAMINE

*To the Editor:*—Does arsphenamine cause sclerosis and obliteration of veins more frequently than neoarsphenamine? If it does, can anything be done to prevent this action? After sclerosis has occurred in veins as a result of arsphenamine therapy, is there any adequate form of treatment that will make them normal again?

HARVEY L. JORGENSON, M.D., Kenosha, Wis.

ANSWER.—There is no more sclerosis and obliteration of veins caused by arsphenamine than by neoarsphenamine, if the preparation is given properly. The average case of sclerosis of the veins following the use of arsphenamine is due to improper percentage of alkali in the solution. If one is careful to follow the technic advised by the United States Public Health Service, 0.85 cc. of tenth normal sodium hydroxide to each tenth of a gram of arsphenamine, the solution that results will not cause irritation of the veins. Moreover, in using a tenth normal solution of sodium hydroxide one should be careful to have it retitrated from time to time, as possibly from evaporation or other cause it may become more concentrated and then the preparation would be too alkaline and would cause an endophlebitis with resultant sclerosis. If one is using arsphenamine in the treatment of syphilis, it is well to give it by the gravity method with a two way valve cock, using physiologic solution of sodium chloride first to see that the needle is in the vein and following up the administration of the arsphenamine by thoroughly flushing out the vein with a further larger amount of saline solution. This would also tend to obviate any damage from a too alkaline solution of the arsphenamine. Once sclerosis has formed in the veins, there is nothing to be done for them.

## SWELLING OF LIPS

*To the Editor:*—A girl, aged 17 years, had an attack in which her lips became swollen, bluish and painful. Thinking of angioneurotic edema, I gave her ephedrine sulphate, which did not relieve the condition. She felt well otherwise. I prescribed calcium and salts, and the swelling subsided slowly. Itching, peeling and discomfort in the lips are still present. I have advised changing her brand of toothpaste to a mild, nonirritating brand. Can I do anything more to relieve her? What tests can be done to help make a diagnosis? Please omit name.

*M.D., Wisconsin.*

ANSWER.—The swelling might well have been due to angioneurotic edema. Against this assumption, however, is the fact that no previous attacks had occurred and that after the swelling subsided peeling took place, which is uncommon in true angioneurotic edema and makes one suspicious of some infectious process or an insect bite or trauma rather than hypersensitivity. The patient should be watched for further attacks, if any. If swellings recur, the diet should be scrutinized, especially for some unusual food. Contact with some irritant, such as a cosmetic, should be thought of. Drug idiosyncrasy must also be taken into account. Protein sensitization tests are frequently successful in angioneurotic edema; elimination diets are often of great help. For symptomatic treatment of the swellings probably the best is epinephrine hydrochloride, 1 : 1,000, from 0.5 to 1 cc., subcutaneously; ephedrine hydrochloride by mouth, from 0.025 to 0.050 Gm. (⅜ to ¾ grain) comes next. Administration of calcium is harmless, though its efficacy is questionable.

## COLD FEET

*To the Editor:*—A girl about 9 years of age has cold feet. The mother says that as a baby the child had to have warm socks at times when other children were wearing none. The girl is normal in every ordinary way: well developed, a good scholar, good disposition and all that sort of thing. There is no evidence of unbalanced circulation, excepting at the feet. Please suggest an explanation and treatment to make skating and other sports more enjoyable. Please omit name.

M.D., Connecticut.

ANSWER.—With the unusual coldness of the feet, coarctation should be excluded as a possible cause of lessened blood supply. The color reactions to cold should be carefully studied to exclude early manifestations of Raynaud's disease. Diathermy might be tried over the area of the second, third and fourth lumbar ganglions to see whether the temperature of the feet becomes normal. The cold feet may be due to a hyperactivity of the sympathetic nervous system. Unless something more than cold feet is found, one may simply resort to additional thickness of stockings, together with an attempt to increase vascular tone by contrast baths to the feet, hot thirty seconds, followed immediately by cold fifteen seconds, hot fifteen, cold fifteen and hot thirty, twice a day.

In skating, constricting straps about the feet and ankles should be avoided.

## COMING EXAMINATIONS

ALABAMA: Montgomery, July 11. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

AMERICAN BOARD FOR OPHTHALMIC EXAMINATIONS: Montreal, Sept. 19. Sec, Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

ARIZONA: Phoenix, July 5-6. Sec., Dr. B. M. Berger, 12 North Central Ave, Phoenix.

CALIFORNIA: San Francisco, July 11-14. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, July 5. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

CONNECTICUT: *Regular.* Hartford, July 12-13. *Endorsement.* July 26. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic.* New Haven, July 12. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

DISTRICT OF COLUMBIA: *Basic Science.* Washington, June 29-30. *Regular.* Washington, July 11-12. Sec, Dr. W. C. Fowler, 203 District Bldg., Washington.

HAWAII: Honolulu, July 11-14. Sec., Dr. James A. Morgan, Room 48 Young Bldg, Honolulu.

ILLINOIS: Chicago, June 28-July 1. Supt., Mr. Paul B. Johnson, Springfield.

INDIANA: Indianapolis, June 21-23. Sec., Dr. William R. Davidson, 413 State House, Indianapolis.

KANSAS: Kansas City, June 21-22. Sec., Dr. C. H Ewing, Larned.

MAINE: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, Jr, 192 State St., Portland.

MARYLAND: Baltimore, June 21-24. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore.

MASSACHUSETTS: Boston, July 12-14. Sec., Dr. Stephen Rushmore, 144 State House, Boston.

MINNESOTA: Minneapolis, June 21-23. Sec., Dr. E. J. Engberg, 524 Lowry Medical Arts Bldg., St. Paul.

MISSISSIPPI: Jackson, June 28-29. Asst. Sec, Dr. R. N. Whitfield, Jackson.

NATIONAL BOARD OF MEDICAL EXAMINERS: Examinations in Parts I and II will be held at all centers where there are five or more candidates, but not at Durham, Minneapolis, nor New Haven, June 27-29. Ex. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia.

NEW JERSEY: Trenton, June 21-22. Sec., Dr. James J. McGuire, 1101 Trenton Trust Bldg., Trenton.

NEW YORK: Albany, Buffalo, New York, Syracuse, June 27-30. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315 State Education Bldg, Albany.

NORTH CAROLINA: Raleigh, June 20. Sec, Dr. John W. MacConnell, Davidson.

NORTH DAKOTA: Grand Forks, July 5-8. Sec, Dr. G. M. Williamson, Grand Forks

OREGON: Portland, July 5-7. Sec., Dr. C. J. McCusker, 1014 Medical Dental Bldg., Portland.

PENNSYLVANIA. Philadelphia and Pittsburgh, July 5-9. Sec., Mr. Charles D. Koch, Dept. of Public Instruction, Harrisburg.

RHODE ISLAND: Providence, July 7-8. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 28. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Waubay, July 19. Dir., Dr. H. R. Kenaston, Bonesteel.

TEXAS: Marlin, June 21-23. Sec., Dr. T J. Crowe, 918-19 Mercantile Bank Bldg., Dallas.

UTAH: Salt Lake City, July 6-8. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

VERMONT. Burlington, June 22-24. Sec., Dr. W. Scott Nay, Underhill.

WASHINGTON: *Basic Science.* Seattle, July 7-8. *Regular.* Seattle, July 11-12. Dir., Mr. Charles Maybury, Olympia.

WEST VIRGINIA: Harpers Ferry, July 12. Sec., Dr. W. T. Henshaw, State Health Dept., Charleston.

WISCONSIN: Milwaukee, June 28-30. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

## New Hampshire March Report

Dr. Charles Duncan, secretary, New Hampshire Board of Registration in Medicine, reports the oral and written examination held at Concord, March 10-11, 1932. The examination covered 12 subjects and included 100 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Two physicians were licensed by reciprocity with other states and 2 physicians were licensed by endorsement. The following colleges were represented:

| College PASSED | Year Grad. | Per Cent |
|---|---|---|
| Columbia Univ. College of Physicians and Surgeons | (1929) | 81 |
| McGill University Faculty of Medicine | (1931) | 86 |

| College LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|
| Tufts College Medical School | (1929) | Mass. |
| Fordham University School of Medicine, New York | (1913) | New York |

| College LICENSED BY ENDORSEMENT | Year Grad. | Endorsement of |
|---|---|---|
| Boston University School of Medicine | (1929) | N. B. M. Ex. |
| Harvard University Medical School | (1929) | N. B. M. Ex. |

## Oklahoma March Report

Dr. J. M. Byrum, secretary, Oklahoma State Board of Medical Examiners, reports the written examination held at Oklahoma City, March 8-9, 1932. The examination covered 12 subjects and included 120 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Three physicians were licensed by reciprocity with other states and one physician was licensed by endorsement. The following colleges were represented:

| College PASSED | Year Grad. | Number Passed |
|---|---|---|
| University of Oklahoma School of Medicine | (1931) | 1 |
| Meharry Medical College | (1929) | 1 |
| University of Wisconsin Medical School | (1931) | 1 |

| College LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|
| University of Louisville School of Medicine | (1927) | N. Carolina |
| Tulane University of Louisiana School of Medicine | (1923) | Texas |
| Columbia Univ. College of Physicians and Surgeons | (1916) | Kansas |

| College LICENSED BY ENDORSEMENT | Year Grad. | Endorsement of |
|---|---|---|
| Washington University School of Medicine | (1928) | N. B. M. Ex. |

## Rhode Island April Report

Dr. Lester A. Round, director, Rhode Island State Public Health Commission, reports the written and practical examination held at Providence, April 7-8, 1932. The examination covered 7 subjects and included 70 questions. An average of 80 per cent was required to pass. Twelve candidates were examined, all of whom passed. The following colleges were represented:

| College PASSED | Year Grad. | Per Cent |
|---|---|---|
| University of Maryland School of Medicine and College of Physicians and Surgeons | (1930) | 85.4 |
| Harvard University Medical School | (1929) | 88.5, 89.9 |
| Tufts College Medical School | (1931) | 90.8* |
| St. Louis University School of Medicine | (1929) | 86.6 |
| Hahnemann Medical College and Hospital of Philadelphia | (1931) | 85.8,* 87.7,* 89.4* |
| Jefferson Medical Colleg |  | 92.3 |
| Marquette University Sc |  | 80.1 |
| Dalhousie University Faculty of Medicine | (1928) | 89.2 |
| Laval University Faculty of Medicine | (1931) | 84.5 |

* Certificates being withheld pending completion of internship.

## Wisconsin Reciprocity Report

Dr. Robert E. Flynn, secretary, Wisconsin State Board of Medical Examiners, reports the oral and practical examination for reciprocity and endorsement candidates held at Milwaukee, April 6, 1932. Fifteen candidates were examined, all of whom passed. The following colleges were represented:

| College LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|
| Rush Medical College | (1929), (1931, 2) | Illinois |
| University of Illinois College of Medicine | (1922), (1926) | Illinois |
| Indiana University School of Medicine | (1930) | Indiana |
| Univ. of Minnesota Med. School | (1929),* (1930),* (1932, 2) | Minnesota |
| Ohio State University College of Medicine | (1929) | Ohio |
| Marquette University School of Medicine | (1931) | Illinois |
| Western University Faculty of Medicine, Ontario | (1909)* | N. Dakota |
| Osteopath † |  | Iowa |

| College LICENSED BY ENDORSEMENT | Year Grad. | Endorsement of |
|---|---|---|
| Harvard University Medical School | (1929) | N. B. M. Ex. |

* Licenses are being withheld pending completion of credentials.
† Licensed to practice osteopathy and surgery.

## Ohio Reciprocity Report

Dr. H. M. Platter, secretary, Ohio State Medical Board, reports 20 physicians licensed by reciprocity with other states, April 5, 1932. The following colleges were represented:

| College LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|
| University of Arkansas School of Medicine | (1929) | Arkansas |
| Indiana University School of Med. | (1924), (1929), (1930) | Indiana |
| University of Kansas School of Medicine | (1928) | Kansas |
| University of Louisville School of Medicine | (1926), (1931) | Kentucky |
| Baltimore Medical College | (1907) | New York |
| Univ. of Mic | 2) | Michigan |
| Washington | 09) | Missouri |
| Cornell Univ | 04) | New York |
| Fordham Un | 21) | New York |
| University of Pennsylvania Department of Medicine | (1903) | Penna. |
| Meharry Medical College | (1926), (1927) | N. Carolina |
| University of Wisconsin Medical School | (1930) | Wisconsin |

## A CONSULTATION SERVICE FOR PATIENTS OF MODERATE MEANS

GEORGE BAEHR, M.D.
NEW YORK

A consultation service for people of moderate means was inaugurated at the Mount Sinai Hospital, New York, Nov. 24, 1931. A brief report on its activities and its future possibilities seems warranted by the widespread interest, both favorable and critical, which this type of public service has heretofore aroused.

The service was established by members of the medical staff of the Mount Sinai Hospital, in cooperation with the board of trustees of the hospital, and is restricted to patients of moderate means referred by their family physician. It is designed as an aid to the physicians of the community in the investigation of patients with clinically obscure conditions requiring multiple consultations and laboratory examinations in order to establish a diagnosis. The service is based on the conviction that the full advantage of competent medical care can best be achieved under the continuous guidance of a family physician but that, in order to accomplish this, he must be provided with complete and easily available diagnostic facilities to supplement his own resources.

Diagnostic clinics heretofore established have met with one or more of the following criticisms:

1. The clinics accept patients who are not referred by physicians, carry out all forms of therapy, and thus practice medicine in competition with the family practitioner.
2. The clinics are manned largely by physicians who do not possess adequate scientific training and clinical experience.
3. Some diagnostic clinics are merely part of a general public dispensary, and the primary principle—to keep the patient in the hands of his physician—is in conflict with the function of the public dispensary which takes over the complete management of the poor patient.

### THE MOUNT SINAI PLAN

The Mount Sinai Consultation Service is organized, staffed and administered by internists, surgeons and specialists who are members of the visiting staff of the hospital proper. It functions as an independent detached unit of the hospital and occupies space in the hospital's new building for semiprivate patients. No patients are accepted unless referred by their physicians. The work is limited exclusively to diagnosis. On completion of the clinical investigation, the patient is promptly returned to the referring physician, who receives as complete a diagnostic opinion as possible, together with detailed advice concerning appropriate therapy. No therapy is practiced, but the physician who refers a patient is invited to avail himself of the advice and guidance of the staff in carrying out the therapeutic procedures recommended.

As the aim of the service is to cooperate with practitioners in the medical care of people of limited means, the economic level of eligibility is a maximum income of $2,400 a year for unmarried individuals and $4,000 for total family income. For families of more than five members, an extra allowance of $400 may be added for each additional dependent. Physicians are requested to refer only patients who fall within this economic group and the patients are expected to give satisfactory information concerning salaries or other income, rent and the names of employer and landlord.

A flat fee of $35 is charged all patients regardless of the nature of their illness or the number of consultations or laboratory examinations that may be required. To avoid interference with the practice of individual consultants, the fee for a comprehensive examination is purposely set at about double the average amount charged a patient of this class by a specialist for an individual consultation or major laboratory examination. It is the intention of the service to maintain a flat fee schedule in preference to a sliding scale. Its obvious advantages are that (1) the patient knows the total maximum cost in advance irrespective of the nature of the condition that may be found and the number or complexity of the diagnostic procedures that may prove to be necessary; (2) the physicians of the consultation service do not find themselves restricted in the thoroughness and completeness of their diagnostic investigation by the patient's financial limitations.

### CLINICAL ROUTINE
